the power of the cylinders shall be able to cause the driving-wheels to slip. Ability to start heavy trains is secured by giving a relatively small diameter to the driving-wheel, while very high speed requires a relatively larger diameter of the wheel, inasmuch as the circumference of the driver measures the space through which the engine will move forward in one revolution, which corresponds to two traverses of the piston. If the driver is too small for a high speed the number of revolutions per minute will become excessive.

In the traction-engine for hauling upon common roads, where the speed is relatively low, it is usual to reduce the speed of the driving-wheels from that of the engine-shaft by intermediate gearing. The driving-wheel also needs to have a tire of great breadth to distribute the weight of the boiler and engine over a large area of yielding roadway. The tires are also usually corrugated or roughened to give adhesion. The traction-engine must have a very efficient means for steering it to enable it to make the sharp turns required in ordinary roads, and it is furthermore usually so designed that by throwing out the intermediate gearing from connection with the traction-wheels, the steam-engine proper can be used as an agricultural engine for threshing, milling, and other similar purposes.

The marine engine of transatlantic practice is usually an inverted vertical compound or triple-expansion, double-acting reciprocating engine. The cylinders are supported on massive cast-iron or cast-steel frames shaped something like a letter A, while the revolving shaft is below the cylinder and between the frames so as to secure immersion for the

a long stroke and a long connecting-rod without taking up valuable deck-room desired for cargo space in vessels of little depth of hull. On the other hand, when conditions necessitated such exceeding shallowness of hull, due to very light draught of water, that the concentrated weight of the vertical cylinder and the overhead beam became impracticable, there was developed a type of horizontal engine with long stroke and small diameter of cylinder, so that the weight of the engine might be distributed over a long length of the hull. The rapid current and tortuous channel of Western rivers suggested also the advisability of making the paddle-wheels on the two sides operate by separate cylinders, with a further advantage in distributing the weight of the engine. Furthermore, for towing on such rivers a type of steamer with the water-wheel at the stern has been developed, the wheel driven by cranks at each end of the shaft which are operated by long connecting-rods, one at each side. Great advantage has followed, where absence of ice makes the practice possible, from arranging the floats of paddle-wheels so that they will enter the water and leave it perpendicularly. The radial float tends to lift the vessel as it strikes, and to lift the water as it leaves; the perpendicular or feathering paddle produces all its effect in propulsion, without wasting a lifting effort. Feathering is secured by connecting the floats by a system of linkage which appears in several different forms.

For land engines and stationary practice probably the five most widely extended uses which involve the largest units are for pumping, for electric lighting and power, for mill and manufacturing purposes, for hoisting and air-compressing

in mining, and for driving the roll-trains of iron and steel works.

For pumping, in addition to the Cornish engine, mentioned above, the two great types most usual are the beam-engine and the direct-acting pumping-engine. The older form of beam-engine was a single cylinder condensing-engine with overhead beam. The beam gives most convenient attachment for connecting-rods and plungers. More recently the compound and triple-expansion

FIG. 10.

screw or propeller at the stern (Fig. 10). In the triple engine the cranks stand at angles of 120 degrees from each other, securing a good distribution of the turning effort upon the shaft. The cross-heads of the first and last cylinders usually operate the air-pump, by which the surface-condenser is freed from the condensed steam, while detached circulating pumps force the water of the ocean through the tubes to cool them. Injury to the valves by which the ocean water for condensation enters the engine has been the occasion of some noteworthy disasters to transatlantic vessels. The turning effort of the engine-shaft is transmitted from the engine to the propeller through a long shaft provided with the necessary bearings, and, in particular, a massive thrust-bearing, upon which is imposed the resistance to endwise motion which the reaction of the screw exerts as the vessel is forced forward. The thrust-bearing accommodates a series of collars, or enlargements of the shaft, whose area and number are proportioned so as to keep the pressure per inch of surface below that at which lubrication becomes difficult or impossible.

For the side-wheel vessel the necessity for having the center of the water-wheel shaft elevated above the water a distance nearly equal to the radius of the wheel has made the beam-engine and the inclined direct-acting engine the type most frequently met. Oscillating cylinders have been used in the past, but are not likely to be selected for large designs in the future. The inclined engine in the earlier practice was a simple condensing-engine; it has been made more recently compound and triple expansion. The advantage of the inclined type is that the center of gravity of the engine is low; the advantage of the beam type has been the flexibility which that construction permits, and that it secures a high piston-speed with a relatively small number of revolutions imposed by the large paddle-wheel, and allows

tion types have come forward, with either the beam below the cylinders or employing a beam of angular type, to various points of which are attached the rods to the fly-wheel shaft and to the pumps. An objection to the use of the fly-wheel in massive pumping-engines is its tendency alternately to accelerate and retard the flow of water in the main as the varying crank angle permits the piston to change its velocity. The direct-acting pumping-engine has no fly-wheel, but is so constructed that it can not stop when its stroke is completed by the expedient of having the valve which distributes the steam in the cylinder operated by another or an auxiliary engine, which latter receives its steam by the action of the piston of the main engine. This arrangement makes it impossible for the engine to stop with both steam passages covered by the valve. If this second or auxiliary steam-engine is made also to be a pumping cylinder, the type of direct-acting pump known as the duplex pumping-engine results. This type prevails very largely, and besides the advantage of having no fly-wheel and no dead center, it offers the advantage of keeping the column of water always in motion, while a moment's pause at the end of the stroke of each cylinder permits the valves in that cylinder to seat themselves quietly before the return stroke begins. In some recent designs the horizontal type has been selected with fly-wheel and vertical beams.

For electric-light and power stations, and for electric railways, the type of horizontal engine, simple or compound, has been much used, the power being distributed among a large number of small units. In more recent practice, with larger units, the inverted vertical type, compound and triple expansion, has been extensively introduced, in many cases the revolving armature for the dynamos being continuous with the revolving shaft of the engine.

For both mill and manufacturing purposes the horizontal

engine in tandem, cross-compound, or triple-expansion form has been by far the most widely distributed. The fly-wheel of such engines is usually made with a broad face, so as to be used as a belt or band wheel from which the power could be taken off to different driven shafts as required. The engines for cable-railway practice are usually of this type, but instead of flat belts, round ropes bearing in grooved pulleys are much more generally applied.

For hoisting-engines in mines and for elevator service it is usual to reduce the speed of the engine-shaft to that of the shaft which carries the hoisting-drum by means of toothed wheels or gearing; this permits the use of cylinders of smaller diameter operating at a high speed with the corresponding advantages. In air-compressing and blowing engines the horizontal and vertical type are very usual, the steam and air pistons being upon the same rod, and two connecting-rods from a cross-head between the two cylinders being coupled to crank-pins on the fly-wheel shaft. These air-compressing and blowing engines require a heavy fly-wheel by reason of the fact that the resistance is least at the beginning of each stroke, so that energy must be stored in them if the engine is working expansively, to be given out at the end of the stroke when the effort of the expanding steam is the least. For rolling-mill engines both horizontal and inverted vertical engines are used, in most cases connected directly to the train of rolls. The great variation in the resistance met by the rolls requires a very massive fly-wheel construction.

The requirement that the piston in the engine cylinder shall admit steam alternately upon its one side and the other, and shall at the same time discharge exhaust steam from one end while receiving live steam from the boiler at the other end, has given rise to a great many different types of mechanism for this purpose. The simplest type is a single valve, sliding upon a flat surface made at a convenient place on the side of the cylinder. The valve is caused to slide by means of a crank or eccentric, usually upon the revolving shaft, and so important is this function in the operation of an engine that space must be taken for a full description of the fundamental forms.

Fig. 11 represents a section of an engine-cylinder by which the action of the common D slide-valve (so called from

FIG. 11.

the shape of its section) may be explained. In this section V represents the valve, situated in a rectangular box or casing, which is in full communication with the boiler when the engine is running. This box, called the *steam-chest*, situated on the side of the cylinder and forming part of it, is constantly full of steam at nearly the boiler-pressure when the engine is in motion. S S are passages called steam-passages leading from this chest to the ends of the cylinder; E, a passage called the exhaust-port leading to the open air or to the condenser. The ports are long rectangular openings in a plane surface on the side of the cylinder. The valve V has such form and dimensions that it covers all these ports when in its neutral or middle position, and is caused to slide back and forth just enough to uncover alternately the steam-ports S S, the amount of this sliding, even in the largest engines, in which the valve may have a super-

ficial area of several square feet, being only 3 or 4 inches. In small engines the extent of sliding in one direction may be only a fraction of an inch. This movement of the valve to the right and left is produced by means of an eccentric or small crank and a special connected rod attached to the valve, by which its motions are made to correspond in point of time with the motions of the piston; but the eccentric and main crank being keyed to the shaft in different positions, these motions, although taking place in the same times, will not at each moment correspond in direction or velocity.

It will be seen from the figure that the piston is at the end of its stroke, and its return to the opposite end depends on its receiving the impulse of steam admitted from the steam-chest just at this moment to drive it back. It will be observed, also, that the valve has been moved from its central position, covering all the ports, already sufficiently far to open the steam-port on the right a small amount, and steam is already admitted and fills the narrow space to the right of the piston. Thus the full boiler-pressure, or nearly so, is already acting on the right of the piston to drive it back. The condition of things on the left of the piston at this moment is quite different. The steam which has been confined in that part of the cylinder to the left, and which by its expansive action has driven the piston toward the right, is free to pass from this space into the atmosphere back through the steam-port S through which it came, but not into the steam-chest—the port S leading through the hollow of the valve to the exhaust-port; and this opening is by the movement of the valve already larger than the opening for admission on the right. The phenomena which take place while the piston moves from the right to the left are as follows: The valve completes its excursion to the left, and returns, so as to shut off the supply of steam on the right of the cylinder, while the piston is still in motion to the left. After the supply is cut off, the confined steam continues to act by its expansion alone, no more being admitted. The fraction of the stroke at which this occurs depends on the dimensions of the valve and the arrangement of the mechanism by which it is moved. It may happen, also, that by the same movement of the valve on its return to the right, and while the piston is still moving to the left, the exhaust-passage is closed so as to confine a portion of the steam in the left-hand part of the chamber, to act as a sort of cushion. This will occur at the moment the inner edge of the hollow part of the valve on the left reaches the inner edge of the steam-port. As the valve continues to move to the right, the outer edge of the valve on the left approaches the edge of the steam-port, and at a certain instant opens that port, letting new or "live" steam from the boiler into this end of the cylinder, which mingles with the exhaust steam already confined there as a cushion. This phenomenon usually takes place but an instant before the piston reaches the end of its stroke, in order that it may meet not only a cushion of exhausted steam, but of steam at full pressure from the boiler.

Fig. 12 represents on a larger scale a section of a simple

FIG. 12.

slide-valve and the cylinder ports, the valve being in its middle or neutral position, covering all the ports. The projection of the outer edges of the valve beyond the edges of the steam-ports, so that the ports are more than covered by the valve, is called the *outside lap*. It exercises an important influence on the distribution of the steam. The projection of the inside edges of the hollow part of the valve over the inner edges of the steam-ports is called the *inside lap*; it is always relatively small, and often does not exist to an appreciable amount.

The adjustment of the single slide-valve with a single eccentric, when once made, can not be easily changed while

Governor Cut-offs.—Devices for cut-offs adjustable by the governor are very numerous. The old combination of the governor and throttle-valve is not a cut-off. Its action is to diminish or increase the pressure in the cylinder as the speed of the engine is increased or lessened, and thus diminish or increase the work per stroke; but a diminution of the initial pressure in the cylinder and the pressure throughout the stroke entails waste of heat and power, and is therefore only admissible where these considerations are not regarded as important. In stationary engines employed for many purposes it is not only important in point of economy that this waste should be avoided, but the character of the work may be such that variations of speed, to any considerable degree, are to be avoided. The action of the governor in causing a complete cut-off of the steam at any point of the stroke depends primarily upon the speed of the engine by which it is moved (see GOVERNORS), and secondarily upon its connection with the valves which close the steam-ports. The power of the governor is not sufficient, generally, to move these valves directly, and hence its action consists in nearly all cases in throwing into or out of gear mechanism driven by the engine itself; by which the requisite movement of the valve is produced. One mode consists in a sudden disconnection of the mechanism which moves the valve, which is then driven back so as to cover the steam-port by means of a weight or spring. The closing of the valve is thus almost instantaneous—a matter of importance both in the opening and closing of the valves. The Corliss engine furnishes an instance of this kind of cut-off. Fig. 17 repre-

Fig. 17.

sents a section of the cylinder of a Corliss engine, with its four valves—the exhaust-valves and the steam induction-valves. The cut-off mechanism is exhibited in this figure, in which A represents a side elevation of the cylinder. The steam-valves move about axes projecting at *i i*, the exhaust-valves about axes at *E E*. *W* is a plate mounted on an axis projecting from the side of the cylinder. It performs the part of a "rocker" simply, being moved backward and forward by the eccentric-rod, *c*. The lever-arms of the lower or exhaust valves are connected with this "wrist-plate" by two links, *l l*, which are permanently adjusted, so as to cause the exhaust to take place at the proper moment. The upper corresponding lever-arms for the induction valves have the form of bell-cranks, to one arm of which a weight is attached by a long vertical rod, shown in the drawing. The links, *r r*, attached to the wrist-plate are not permanently jointed to the bell-cranks, but the ends of these links or bars slide along the ends of the bell-crank; a notch in the sliding end catches the arm on the return motion and draws it back, opening the valve. The disengagement of this notch is effected by a bent piece, shown at *b*, which, as the link, *r*, is drawn back, strikes a small protuberance, *p*. The position of this small protuberance depends only on the governor. The governor-rods, *g g*, are attached to the ends of levers which move plates or rings embracing the axes, *i i*, and on these plates the protuberances are made. When the hook or bent piece strikes the protuberance, the notch is disengaged, and the weight, acting on the valve, closes it. The cutting off of the steam is thus instantaneously effected.

Another example may be given to illustrate the use of a cam-motion controlled by the governor. Fig. 18 represents a section of the cylinder of such an engine; *V V* the valves, which are balanced poppet-valves. These valves are double—that is, they have two conical seats—and when they are closed, the steam-pressure acting on both sides of the valve, it is nearly balanced. The stems of these valves extend to a position near the middle of the cylinder, and are there

actuated by a cam, *C*, being alternately opened by the cam. When the cam in its revolution releases either valve, it is carried back promptly by a spring. The cam slides vertically on a rod, the vertical motion bringing a new arc of

Fig. 18.

the cam into action. This vertical motion is controlled by the governor. Other efficient devices might be mentioned which are deservedly popular, but these are sufficient to illustrate the principle. The Stevens cut-off, so common on U. S. river-steamers, has poppet-valves, the vertical valve-stems having strong toes or projections attached to them which are lifted by corresponding toes or arms attached to the rock-shaft. This cut-off is not controlled by the governor, but is adjustable by the engine-driver. The Ryder cut-off is one in which by an ingenious device the governor performs the work of moving the expansion-valve unassisted by the engine.

Fly-wheel.—The fly-wheel is an important and essential appendage to the steam-engine under many conditions.

A stationary engine with a single cylinder requires a moving mass between the piston and the working-point, which by its alternate accelerations and retardations will store up and give out energy in such a manner as to keep the power, reduced to or at the working-point, nearly constant. As an example, the rolling-mill is perhaps the most striking. The useful work to be performed is in this case the driving of a heavy plastic bar or plate of iron or other metal between rolls—an operation not continuous, but occurring only at intervals. With a single-cylinder engine of the ordinary type the pressure of the steam on the piston at any instant is not usually sufficient to overcome the great resistance offered; by the interposition of a heavy fly-wheel, however, the action of the engine produces gradually a high velocity of revolution in the fly-wheel, causing an accumulation of energy. When the metal enters the rolls, this accumulated energy is given out; and even if the steam were suddenly shut off, the fly-wheel would carry the metal through the rolls. This is accomplished, however, only at the cost of a loss of velocity in the fly-wheel, which loss must again be restored by the engine. Again, when the resistance is sensibly constant, as when an engine is driving a shop or factory, the power of the engine is nothing at the dead-points, and is a maximum at nearly mid-stroke. If there were no moving mass to store up and give out energy, the engine must cease working at the first dead-point; for at that point the piston, which is the working-point, comes to a stop and begins to return on its course. When, in addition to the above considerations, the action of the steam on the piston is not constant, but diminishes gradually from the time it is cut off, the necessity for the fly-wheel to keep up a uniform or nearly uniform motion in the shaft is still greater; or, rather, the conditions on which its dimensions depend become more complicated. In cases where the energy of the fly-wheel is required for a short period of time to perform nearly the whole useful work, as in the case of a rolling-mill, its dimensions can not be theoretically estimated with certainty. Precedents and experience must then be the chief guides to the engineer. The dimensions suitable for a given engine, in which the resistances are supposed constant, may, however, be determined from theoretical considerations, at least with the aid of experiments made to determine certain constants which enter the formulas. It is impossible to establish a perfect uniformity of motion in the crank-shaft of an engine, because the mass, which by alternately gaining and losing energy preserves a uniform velocity during certain periods of motion, can only act by itself gaining or losing velocity momentarily at intervals of those periods; but under given conditions the variations of velocity may be made as small as is desirable.

The space available permits only a brief discussion of the theory of the action of steam in the steam-engine.

A certain quantity of steam enters the cylinder at each stroke of the piston, depending on the cut-off or degree of expansion. During this period the piston is actuated by

the full pressure of the steam in the cylinder, generally a little less than that in the boiler, and performs a quantity of work represented in foot-pounds by the product of the pressure multiplied by the volume traversed during the period of full pressure, or $p_1 V_1$. After the steam is cut off it continues to act on the piston by its expansive force, but with a constantly diminishing pressure, to the end of the stroke. It is usually assumed in practice that the diminution of pressure takes place during this part of the stroke, according to the law that the pressure is inversely proportional to the volume; and on this supposition the mean pressure throughout the whole stroke is determined by the formula—

$$p_m = p_1 \frac{(1 + \log. r)}{r},$$

p_m being the mean pressure, r the ratio of expansion; the logarithms being taken in the Napierian system. As the piston returns, a certain back or negative pressure is unavoidable, due to the resistance offered by the steam that is being expelled from the cylinder. That pressure can not be determined from theoretical considerations, but it is approximately known from experience.

FIG. 19.

In engines in which the grade of expansion may be varied at will, the power of the engine will correspondingly vary. The engine making n revolutions per minute, the distance passed over by the piston per minute will be $2nS$, which varies in practice from 200 to 800 feet. The formula is evidently a purely mechanical one—i. e. the force of the steam is treated as though it were any other force subjected to like variations, and acting upon the area of the piston. Questions of the quantities of heat do not enter. The action of this force is usually illustrated by a diagram as follows (Fig. 19): Let $OD = S$ represent the length of stroke of the piston; $AB = S_1$ the distance passed over by the piston before the steam is cut off. The ratio of expansion will be $\frac{S}{S_1} = r$, and that will be equal to the ratio of the volumes $\frac{V}{V_1}$ of the steam at point of cut-off and at the end of the stroke. Let $OA = p_1$ represent the initial pressure of the steam in pounds per square inch; then $p_1 A \times 144$ will represent the total force on the piston $= P$. The work performed during the travel from O to H or A to B will be represented by PS_1 , or $A \times p_1 S_1 \times 144$. The area of the rectangle $OABH$ will then represent this work. The work performed during the travel from H to D will in the same manner be represented by the area $HBCD$, on the assumption that the curve BC is an equilateral hyperbola. This area will be equivalent to $PS_1 \log. r$, and the sum of these two areas representing the whole work of the steam during one stroke,

$$PS_1(1 + \log. r).$$

It is assumed, further, that on the return of the piston the steam that filled the cylinder is discharged at a constant pressure, and that the fall of pressure at the end of the stroke, as well as the rise of pressure on the entrance of the steam, takes place suddenly while the piston is at rest. The area of the rectangle $OEDF$, subtracted from the sum of the areas given above, will then give an area, $EABCF$, which represents the work performed. The area $EOFD$ is represented by $p_2 V_2$, the value of p_2 being assumed.

The "efficiency" of a machine is a term used to designate the ratio of the disposable or theoretical work to the useful work. This is the usual mode of estimating the loss of effect in employing any machine. If the disposable work is estimated in the cylinder of the steam-engine in the theoretical manner above indicated, calling W the disposable work and W' the real work, the efficiency will be $\frac{W}{W'}$, a fraction always less than unity, because, on account of friction, there is always in any machine a certain amount of useless or ineffective work. There are generally also other causes of loss, so that the efficiency of a machine becomes still less.

The efficiency of machines can be determined, therefore, only when the disposable work W and also the useful work W' can be determined.

In estimating theoretically the power of an engine furnished with a steam-jacket, it is impossible to assume with certainty the actual conditions of the problem. It is not known, for instance, precisely what quantity of heat will be furnished by the steam-jacket, nor what relative quantities of vapor and water will be found in the cylinder at the beginning of the expansion. It is usually assumed that enough heat enters the cylinder from the jacket during the expansion to prevent the condensation which would occur if no heat were added—i. e. if there were no steam-jacket; that the curve of expansion is the curve of quantity of vapor constant, and that the steam is saturated and dry at the beginning of the expansion. The curve of expansion is then represented by Rankine by the formula

$$PV^{1.05} = P_1 V_1^{1.05} \text{ or } P = C_1 \frac{1}{V^{1.05}} = C \frac{1}{V^{1.1}},$$

and the mean forward pressure is given by the formula

$$p_m = p_1 \left(17 \frac{1}{r} - 16 \frac{1}{r^{1.1}} \right),$$

r being the ratio of expansion. The mean effective pressure ($p_m - p_2$) is then known when p_2 is assumed.

The application of purely theoretical rules to the expansion is complicated by an important secondary phenomenon which can not well be submitted to analytical investigation. The cylinders of ordinary engines are made of cast iron, which takes up and gives out heat as a sponge takes up and gives out water. On this account, the expansion line of actual engines differs so much from any theoretical line that can be drawn that it is only from experiments with the indicator that the effect of this interchange of temperature between the iron cylinder and the mixed steam and water can be determined.

The use of the steam-jacket, or annular casing enveloping the cylinder with hot steam from the boiler, is an economizer of heat, not because condensation during expansion by the adiabatic curve is in itself a loss of heat, but because the presence of liquid water in the form of cloud, or in any other form, in the cylinder facilitates and renders more rapid the interchanges of heat with the metal of the cylinder and the hot steam entering from the boiler. Thus the initial pressure is diminished and the final pressure is increased in a way that can not be estimated theoretically. As nearly all engines work expansively, it is therefore generally impracticable to ascertain theoretically, except as a mere approximation, the quantity of work which an engine under given conditions is actually exerting. The only true resource is the indicator.

The following table gives the quantity of vapor required per horse-power per hour for an ideal engine:

Pressure in atmospheres.	Pounds of water or vapor per horse-power per hour.	
	Non-condensing-engines.	Condensing-engines.
1½	78.9	15.6
3	38.3	12.9
4	26.7	12.0
5	23.2	11.5
6	21.0	11.0
8	18.3	10.4
10	16.7	10.0

The efficiency of a steam-engine in actual use may be ascertained by comparing the quantity of steam actually used to give one horse-power per hour with the quantity given by the above table for the same initial and terminal pressures of the steam. For instance, a non-condensing-engine may give a horse-power per hour with a consumption of 35 lb. of water or steam at a pressure of 6 atmospheres—a common performance. The theoretical quantity required in a perfect engine, according to the preceding table, for the same initial pressure is 21 lb. The efficiency of the engine under these circumstances, measured by the standard of steam required, is $\frac{21}{35} = 0.6$. Ordinary boilers of the best type may evaporate 9 lb. of water for 1 lb. of coal burned, the maximum of evaporation of the boiler being about 13.5 lb. of water per pound of coal. The efficiency of the boiler is then $\frac{9}{13.5} = \frac{2}{3}$. Multiplying these efficiencies together, we have the efficiency of the boiler and engine equal to $0.6 \times \frac{2}{3} = 0.4$.

The efficiency of the apparatus, measured by the ratio of the work in foot-pounds accomplished to the number of

foot-ponds of work, which are equivalent to the heat evolved in the combustion of fuel, gives a different result. A non-condensing engine that requires 25 lb. of water per horse-power per hour will require a consumption of about 4 lb. of coal per horse-power per hour, of which only about six-tenths are available, the other four-tenths being waste heat of the boiler, heat required to produce the draught, etc. One horse-power per hour is equivalent to 1,980,000 foot-ponds per hour of actual work. The available heat of combustion of 4 lb. of coal is about 24,000,000 foot-ponds. The efficiency of the whole apparatus on the basis of the heat which is imparted to the water by the combustion of the fuel will be $\frac{1,980,000}{24,000,000} = .08$, approximately.

In condensing engines a corresponding calculation will give an efficiency of .17, a horse-power per hour being produced by 15 lb. of coal in some instances. The efficiencies of the non-condensing and condensing engines approach each other as the initial pressure increases.

It may be stated, as a general conclusion, that the use of a compound with a single cylinder under ordinary circumstances results in an important saving of fuel, especially for high degrees of expansion; that in the compound engine, with the larger cylinder jacketed, there is a saving in economy over a single cylinder jacketed, even with the same steam pressure and degree of expansion in both. This last conclusion, although derived from what appear to be convincing and satisfactory experiments, is perhaps not universally accepted by engineers, the subject being one about which there is still considerable discussion. Large cylinders are more economical in expenditure of fuel for a unit of power than small ones, and slow-speed engines generally less economical than high-speed engines. An engine using steam at high pressures, other things being equal, is more economical than one using steam at low pressure. In regard to the degree of expansion to be allowed in designing an engine, it is to be observed that the point of cut-off with a given pressure determines the mean pressure in the cylinder; and if the speed of the piston be fixed the size of the cylinder is determined.

There is still a want of precise and definite rules for ascertaining the most economical degree of expansion in every given case; and hence a theoretical calculation of the dimensions of the cylinder of an engine to be constructed is a problem which involves some degree of uncertainty as to maximum economy. In a paper presented to the American Society of Civil Engineers by Dr. C. E. Emery, M. E., in 1874, giving an account of experiments made by him for the U. S. Navy Department, the following formula is given, based on the experimental data for the most economical ratio of expansion in a single cylinder:

$$r = \frac{p+37}{22}$$

in which r is the ratio of expansion, p the initial pressure above the atmosphere. For example, taking p equal to 5, 10, 25, 40, 60, 80, 100, the values of r will be 1.9, 2.1, 2.8, 3.5, 4.4, 5.3, 6.4, respectively. Dr. Emery states that these ratios are "nearly correct for single engines of large size, with details of good design, too small for single engines of ordinary construction, and too small for the better class of compound engines." The final performance of an engine can only be satisfactorily tested by the use of the indicator and dynamometer, with condensation of the steam and measurement of the consumption.

Steamer-duck | See DUCK.

Steam-hammers, hammers which are raised by the direct action of steam on a piston in a steam-cylinder, as distinguished from hammers which are raised by other mechanical means, receiving their power from a steam-engine through the intervention of belts and pulleys or gearing. A heavy mass of iron constitutes the hammer, or "tip," as it is called. This tip slides freely in guides or ways in the frame or upright of the hammer. On top of this frame is placed a cylinder fitted with piston, piston-rod, and valve, after the manner of a steam-engine. The piston-rod, extending downward through a stuffing-box in the bottom cylinder-head, terminates in its attachment to the tip or hammer. Steam admitted under the piston raises it and thus lifts the hammer; upon the opening of the exhaust and escape of the steam the hammer falls with a force due to its weight, less the friction of the piston, piston-rod, and escaping steam. This form of hammer was at first made single-acting only, that is, the steam is used only beneath the piston, but hammers are now commonly made double-acting, the pressure of the steam above the piston in the down stroke assisting the action of gravity, thus causing the hammer to strike a more rapid and more powerful blow.

The first practical steam-hammer, it is generally stated in English treatises, was invented and constructed by James Nasmyth, of the Bridgewater Foundry, Patricroft, near Manchester, England. He had proposed the construction of such a hammer for forging the paddle-wheel shafts of steam-going steamers in 1857. It is also claimed that the steam-hammer was invented by François Bourdon, in France, in 1839; and one was built from his designs by the Croust iron-works in 1841. Earlier patents upon steam-hammers were taken out in England, by James Watt, in 1794, and by William Dorell in 1806, but there is no reason to believe that these patents were ever worked.

Nasmyth's first hammers—single-acting only—were worked by hand, but his engineering manager, Robert Wilson, hit upon a plan of operating the valve automatically; and he also, it is believed, first applied the balance principle of valve to the steam-hammer.

Steam-hammers have more cause to deteriorate in use than almost any other machine tool, inasmuch as the severe shocks to which they are submitted while in use tend to destroy their parts. In the earlier hammers the piston-rod seems to have been the part which gave the greatest trouble, and many inventions were made to remedy the defect.

Robert Morrison, of Newcastle-on-Tyne, in 1852 patented a steam-hammer in which the piston-rod was the hammer, and the blow was imparted by the end of the piston-rod properly protected by a shoe or hammer-face. He made the piston-rod very large and of wrought-iron, welding the piston to the middle of this long rod, and guiding it by stuffing-boxes in the upper and lower cylinder-heads. To prevent the bar from turning, he cut a flat on the rod above the piston-head, and guided it by a corresponding shape in the top cylinder-head. Hammers for heavy forgings are constructed with double uprights, large-sized hammers with a long stroke, leaving a wide spread of base between the legs of the upright to give room for the work-

FIG. 1

man to handle the iron being forged. The anvil-face is usually set at 15 inches above the floor-level. Fig. 2 shows a double upright hammer of the Morrison type. These large hammers are not made self-setting, as it is found to be more

advantageous to work them by hand. In light work, such as drawing out bars of steel, an automatic valve-motion is of the utmost importance. Fig. 1 shows the form of a single upright hammer as used for light forging. A hammer weighing 300 lb.—i. e. the hammer-bar, or part which strikes the blow, weighing 300 lb.—should make at least 300 blows per minute to work economically in light forging. An important feature in these rapid-running steam-hammers is the separation of the exhaust-passages in the slide-valve, so that the exhaust from the space below the piston escapes through a passage which does not communicate with the exhaust-

FIG. 2.

passage from the space above the piston. In the exhaust-passage from below the piston is arranged a throttle-valve, which when partially closed chokes the exhaust escape, and thus, suspending the escape of steam as the hammer descends, materially diminishes the force of the blow, and yet, inasmuch as the upper exhaust-passage is open, the hammer rises as quickly as when working with full exhaust. This is of advantage in working steel, as the force of the blow can be lessened at will without materially slowing the speed or rapidity of blows.

In setting steam-hammers it is important that the foundations should be of the most substantial character. It is usual to make the anvil-block separate from the hammer, and to place it on a separate foundation which is underlaid with some thicknesses of wood, say with two layers of closely fitted timbers at least 24 inches in thickness. This gives a degree of elasticity to the anvil and preserves the foundation. The anvil for iron-forging hammers should not be less than five times, and for steel-forging ten times, the weight of the hammer. The direct-acting steam-hammer has numerous rivals in iron making and shaping, such as helve and other power-driven hammers, which are found useful in many lines of manufacture; drop-presses, used for drop-forging; driven rolls; and, finally, hydraulic forging-presses. The steam-hammer forges the metal into the required shape with repeated blows and well-directed skill on the part of the workman. In hydraulic forging the red-hot metal may be made to flow in a solid state into metal moulds, and driven into them by plungers operated by hydraulic presses; but the hydraulic press may also be used to compress metal between a flat movable block and an anvil, thus becoming a direct competitor with the steam-hammer. The first cost of hydraulic apparatus, however, limits the extent of its introduction, and the steam-hammer will probably long continue to be one of the most extensively used forms of apparatus for forging iron and steel.

The largest steam-hammer in the world was built in 1891 at the Bethlehem, Pa., steel-works. The weight of tup, piston-rod, and piston aggregates 125 tons. The cylinder is 76 inches in diameter, and the stroke is 16½ feet. The anvil-foundation contains twenty-two blocks of cast iron, averaging 70 tons each, resting upon steel slabs supported by white-oak timbers. The mass of iron and steel in the foundation weighs 1,800 tons.

Steam-vessels: ships propelled by steam. The possible adaptation of steam for the propulsion of ships seems to have occurred to Roger Bacon in the thirteenth century. It has been stated that Blasco de Garay, of Spain, in 1543, propelled a vessel by steam, but La Fuente, the Spanish historian, found that de Garay made (1540-43) trials with paddles on ships furnished by Charles V., but in every case the paddles were moved by men. Suggestions as to the use of steam, none of which were carried out practically, were made by Salomon de Caus (*Les Raisons des Forces mouvantes, avec diverses Machines tant utiles que plaisantes*, Paris, 1615) and the Marquis of Worcester (*Century of Inventions*, London, 1663). The earliest practical effort appears to be that of Papin, who in 1707 applied his steam-engine to the propulsion of a model on the Fulda river at Cassel. Newcomen had in the meantime brought the steam-engine itself to a working condition; and in 1736 Jonathan Hulls patented a marine steam-engine which he proposed to employ in a vessel to be used as a tugboat. About 1763 William Henry, of Pennsylvania, built a small model steamboat, which he tried with success on the Conestoga river; the experiment is notable as having furnished the hint to the efforts made later by Robert Fulton. During the last quarter of the eighteenth century the problem of steam-navigation had begun to engage many minds in Europe and the U. S. In France the Count d'Auxiron and M. Perier made experiments in 1774-75, and the Marquis de Jouffroy, upon a larger scale and with better success, in 1776-83. In the U. S. James Rumsey, of Maryland, was similarly engaged, and in 1786 built a boat which was propelled upon the Potomac by steam at the rate of 4 miles an hour by means of a jet of water forced out at the stern. He built a boat in London with which a successful experiment was made on the Thames in 1792. Meanwhile John Fitch experimented on the Delaware river. His first boat, built in 1786, was propelled by paddles moved by a steam-engine; at first a speed of only 3 miles an hour was attained, but improvements increased that speed to 8 miles. It is noticeable that in his boat he employed side-wheels, with a screw-propeller at the stern. In 1788 Miller, Taylor, and Symington built a boat which consisted of two connected hulls driven by a single paddle-wheel between them, which obtained a speed of 5 miles an hour on Dalswinton Loch. They built a larger vessel in 1789 with a steam-engine of 12 horse-power, which attained a speed of 7 miles. In 1801 Symington built a boat for towing, which drew vessels of 140 tons at the rate of 3½ miles an hour. About 1790 Robert Fulton left the U. S. for England, where he turned his attention to mechanics, and especially to steam-navigation. He made experiments in France, which were only partially successful, but he secured the confidence and aid of Robert R. Livingston, the U. S. ambassador, and in 1806 returned to New York, bringing with him a Boulton & Watt steam-engine, for which a hull was built. This vessel, named the *Clermont*, made a trial trip to Albany, Aug. 7-9, 1807, returning on the two following days, her average running speed being 5 miles an hour. The *Clermont* was 130 feet long, 18 feet beam, 7 feet deep, with a burden of 160 tons. She soon began making regular trips between New York and Albany, and for all practical purposes must be considered the first steamboat adapted for the conveyance of passengers and freight. Fulton and Livingston obtained from New York the monopoly for using steam-vessels in the waters of the State. John Stevens, of New York, was even earlier than Fulton an experimenter in steam-navigation. In 1789 he had perfected his plans for a steam-vessel, and in 1804 and 1805 built small vessels which showed that his plans were sound. The *Phoenix*, his first steamboat, completed in 1807, followed hard upon Fulton's *Clermont*. Prevented by the monopoly of Fulton and Livingston from navigating the Hudson, he sent his boat by sea to the Delaware, upon which she was afterward employed, and in this voyage demonstrated the problem of the possibility of the use of steam-vessels upon the ocean. Steam-vessels in the U. S. were thus an assured success. Fulton and his coadjutors soon placed a fleet of them upon the

[Hudson river and Long Island Sound, while Stevens and his sons placed their steamers upon the Delaware and the Connecticut, and upon the Hudson after Fulton's monopoly had expired. The first steamboat in Great Britain was the Comet, 40 feet long, built in 1812 for the navigation of the Clyde; but before this time Fulton and Livingston had begun to build steamers at Pittsburg, Pa. Upon all navigable rivers and smooth waters of the civilized world steamboats were rapidly introduced, and their use upon the ocean followed. As early as 1819 the steamer Savannah made the voyage from Savannah, Ga., to Liverpool, England, in twenty-two days, and thence to Russia. From that time the development in ocean steamships has been steadily toward larger steamers, including the famous Great Eastern. The Lucania, of the Cunard Line, a screw steamship of steel, 620 feet long and having a gross tonnage of 13,000 tons, crossed the Atlantic from Queenstown to New York in 5 days 7 hours and 23 minutes (Oct. 21-26, 1894).

Revised by MARCUS BENJAMIN.

Stearic Acid [*stearic* is from Gr. *στεάριον*, tallow]: the most abundant of the solid fat-acids; obtained in the saponification of all the fats containing stearin, and especially of beef's tallow, mutton suet, hog's lard, etc. The so-called stearic acid (or stearin) of commerce is a mixture of stearic and palmitic acids. This commercial stearic acid is produced by the treatment of neutral fats by superheated steam or by alkalis. See SOAP.

Saponification of fats by water alone, at a high temperature, was patented by R. A. Tilghman, of Philadelphia, Jan. 9, 1854, and about the same time (Apr., 1854) by Berthelot, who announced that he had resolved the neutral fats with water in closed vessels at a temperature of 428° F. Tilghman specified the preferred temperature of melting lead, 625° F., but names also the melting of bismuth, 518° F., and to promote the reaction caused the mixture of water and fat to traverse small tubes of wrought iron heated in a fire to a pressure of 90 or 100 atmospheres. Tilghman's process, as originally set forth in his patent, was never introduced in practice. The very high temperature employed destroyed the glycerin and contaminated the stearic acid. As subsequently modified, it has been used with success, but, as the courts have decided, not within the limits of the patent. Melsens, of Brussels, almost at the same time with Tilghman took out in Belgium a patent for the use of water slightly acidified by sulphuric acid to act on fats under pressure at a temperature of 356° to 392° F. The presence of a small quantity of sulphuric acid—1 to 10 per cent. of the fat used—favors in a remarkable degree the evolution of the fatty acids. Melsens's method was put into successful operation at Antwerp almost immediately, using a peculiar form of digester, lined with lead, holding a ton of tallow, to which was added 50 per cent. of water, and in six hours the decomposition was complete at a temperature of 356° F. (ten atmospheres), and the fatty acids obtained were very satisfactory.

The possibility of decomposing the fats by water under high pressure was distinctly recognized by Chevreul, who pointed out the perfect analogy between the fats and the compound ethers, which are decomposed when heated in close vessels in contact with water.

George Wilson in 1852 revived the method of decomposing fats at a high temperature, and subsequently distilling off the acids and glycerin separately by a current of superheated steam, originally conceived by Chevreul and attempted by Bussy and Le Canu in 1825, and more successfully by Dubrunfaut in 1841. In 1855 Wilson exhibited to the jury of the Paris Exposition of that year the results of his method on palm oil by means of water and heat alone, distilling off both glycerin and fatty acids in a way to obtain all the products in a state of chemical purity. To this end the oil is heated in a still to the temperature of 550 to 600° F., and then a stream of subdivided, superheated steam passes through it of a temperature of 600° F. Below 550° F. the saponification and distillation of the products is slight; at about 600° F. the distillation is more rapid, but is then accompanied with the production of acroleins. It is by this process that Price's glycerin is produced. This process works well only on palm oil, and is in fact only a slight modification of the previous process of Dubrunfaut. The complete success of the hot-water process was achieved only in 1857 by Wright and Fouché—French patent of 1857, American in 1859. This requires particular mention.

Wright and Fouché's apparatus by hot water alone produces complete decomposition of fats into fat-acids and

glycerin by a continuous and automatic commingling of water and steam with the fat at a pressure and temperature of ten to twenty atmospheres for a period of twelve to twenty hours. No lime is used; water at the temperature named is the sole chemical agent; and the glycerin produced is of excellent quality; the stearic and palmitic acids (after expressing the oleic acid) are white, fine-grained, hard, and free of odor.

Revised by IRA REMSEN.

Ste'arin [from Gr. *στεάριον*, tallow] ($C_{18}H_{34}O_2$) = $C_{17}H_{33}O_2$: a glyceride or ether of glycerin, as shown by the formula *tristearin*. In commercial parlance, *stearin* is a term applied to the impure stearic acid obtained by the saponification of fats in the preparation of star candles. Tristearin is the natural form of stearin in the hard fats of both kingdoms.

Stearns, LEWIS FRENCH, D. D.: theologian; b. at Newburyport, Mass., Mar. 10, 1847; nephew of President William A. Stearns; graduated at Princeton College 1867; studied theology at Princeton, in Berlin, and Leipzig, also in the Union Theological Seminary, New York, where he graduated in 1872. He was pastor of a Presbyterian church at Norwood, N. J., 1873-76, and Professor of History and Belles-Lettres at Albion College, Michigan, 1876-79; Professor of Systematic Theology in the Congregational Seminary at Bangor, Me., 1880, until his death. His inaugural discourse at Bangor (June 1, 1881) attracted much attention for its marked ability. In July, 1891, he read before the Congregational International Council in London a paper of very high merit on the *Present Doctrinal Tendencies of American Congregationalism*. His principal works were the *Lectures on the Evidence of Christian Experience*, delivered at the Union Theological Seminary, New York, in 1890, and subsequently published, and a posthumous volume, *Present Day Theology*. D. Feb. 1, 1892.

GEORGE P. FISHER.

Stearns, WILLIAM AUGUSTUS, D. D., LL. D.: fourth president of Amherst College; b. at Bedford, Mass., Mar. 17, 1805, the son and grandson of Congregational clergymen; graduated at Harvard College 1827; studied theology at Andover, and after teaching a short time at Duxbury was ordained to the ministry, and installed pastor of the Congregational church at Cambridgeport Dec. 14, 1831. In 1854 he accepted the presidency of Amherst College, which he held till his death June 8, 1876. Besides valuable addresses given during his connection with the college he published several sermons, with papers in the *Bibliotheca Sacra*, *Biblical Repository*, and *New Englander*, a work on *Infant Church Membership* (Boston, 1844), and *Life and Select Discourses of Samuel H. Stearns* (1846).

Ste'atite, or Soapstone [*steatite* is from Gr. *στεάριον*, *στειάριον*, tallow, fat]: a kind of stone which receives both its names from its unctuous quality. It is a compact form of talc, and is an impure hydrated silicate of magnesia. It has some use in the porcelain manufacture. A soft white sort is the French chalk of the toilet and of the tailors' shops. Powdered steatite is employed as a lubricant, and is an ingredient in several kinds of steam-packing. Steatite is easily cut into figures, which are then hardened by fire and colored to imitate more costly stones. Steatite is employed in making stoves and foot-stoves for use in cold weather, since it retains heat for a long time. It is abundant in many parts of the U. S. and other countries.

Stebbins, HORATIO, D. D.: pulpit orator; b. at Hampden, Mass., Aug. 8, 1821; educated at Exeter Academy and Harvard College; graduated at the latter in 1848, and from Harvard Divinity School in 1851; received degree of D. D. from Bowdoin College in 1856; pastor of Unitarian churches at Fitchburg, Mass., and at Portland, Me., where during the civil war he made a civic reputation which led to his call in 1864 to the Unitarian church in San Francisco (where he has since remained) as the successor of Thomas Starr King, who had done the Union cause great service with his voice and pen. He has been actively engaged in educational work and in social reforms; has published sermons and addresses and several orations.

JOHN W. CHADWICK.

Steckel, LOUIS JOSEPH RENÉ: engineer; b. at Wintzenheim, Alsace, in 1844; studied engineering and architecture at Quebec; engaged 1861-62 on Gaspé and St. Lawrence road surveys; appointed in 1863 draughtsman of public buildings Ottawa; in 1870 on permanent engineering staff, Public Works Department, Canada; in 1873 assistant engineer on canal, harbor, and river works, Dominion of Canada,

and in 1880 was appointed chief clerk engineering branch, Public Works Department. He is author of *Geometrical Solutions of Difficult Problems in Land Surveying* (1866); *An Essay on the Liquid Contracted Vein*; and various technical reports.

NEIL MACDONALD.

Stedman, EDMUND CLARENCE, LL. D., L. H. D.: poet and critic; b. at Hartford, Conn., Oct. 8, 1833; studied at Yale College; became in 1852 editor of *The Norwich Tribune*, in 1853 of *The Winsted Herald*; settled in New York in 1855; in 1860 was employed upon *The New York Tribune*; was an editor and war correspondent of *The New York World* 1861-63; contributed to *The Atlantic Monthly* and other magazines; was in 1863 in the attorney-general's office at Washington, and has been since 1865 a stockbroker in New York. He is the author of *Poems Lyric and Idyllic* (1860); *Alice of Monmouth, and other Poems* (1864); *The Blameless Prince, and other Poems* (1869); and *Hawthorne, and other Poems* (1877). His *Poems* were collected in a single volume in 1873. He delivered his narrative poem, *Gettysburg*, in 1872 at a meeting of the Army of the Potomac, and his *Ode at Dartmouth College* 1873. Since 1873 he has devoted himself largely to critical work; *Victorian Poets* (1875; 13th ed. with supplementary chapter in 1887) was followed by *Poets of America* (1885), and by *The Nature and Elements of Poetry* (1892), originally delivered in 1891 at Johns Hopkins University as a lecture series on the Percy Turnbull memorial foundation. In 1891 he succeeded James Russell Lowell as president of the American Copyright League. In 1888-90 he edited, with Ellen Mackay Hutchinson, an important *Library of American Literature* in eleven volumes, and in 1895 he brought out *A Victorian Anthology*.

Revised by H. A. BEERS.

Steel [O. Eng. *stēle*; O. H. Germ. *stahel* (> Mod. Germ. *stahl*); Icel. *stál*; cf. O. Pruss. *stakla*. Russ. *stal* is loan-word from Germ.]: a term comprising several modifications of iron. It is necessary to define the term "steel" at some length, since the old classification very inadequately describes the modern cast, malleable compounds of iron, carbon, and metalloids used for structural purposes, and constituting at least three-fourths of the metal now made by steel processes. The old term "steel" referred to the cast malleable product of iron and so much carbon (from $\frac{1}{2}$ to $1\frac{1}{2}$ per cent.) that the metal would harden when heated to redness and quenched in water; it is used almost exclusively for cutting tools. The homogeneity of this metal is, however, an equally distinguishing quality, and is due to its having been poured into a mould while in a fluid state, so that the slag might separate by gravity, and the metal might become solid and crystalline. Wrought iron, on the contrary, while having similar chemical properties, and sometimes as much carbon, consists of pasty masses from which the slag is rarely quite expelled by the pressure that sticks them together; it is therefore laminated in structure. As the soft compounds and those largely varying in chemical constituents came gradually to be produced by casting processes, it was natural and convenient to enlarge the term "steel" to cover them; and the use of the term was at the same time rendered legitimate and scientific by basing the classification on one of the grand characteristics—structure due to casting—rather than on ingredients, as heretofore, especially since structural qualities were constantly increasing in importance. It is found practically convenient to distinguish between all the cast malleable compounds, whether hard or soft, by affixing the name of the metalloid chiefly incorporated, such as chrome steel, manganese steel, and the like, or the percentage of carbon, or both. It is important to know the amount of carbon in structural steels, and this may be readily determined. The general usage of commerce, as well as of works, is rapidly fixing this enlarged definition. As this article is intended to refer to those compounds of iron which are generally known and sold as steel, such as Bessemer rails and open-hearth boiler-plate, as well as tool-steel and spring steel, the definition must for these purposes be as follows: Steel is a compound of iron which has been cast from a fluid state into a malleable mass. The terms "pot" or "crucible" steel, "open-hearth steel," and "Bessemer steel" are convenient for distinguishing processes of manufacture, but they do not necessarily distinguish between steels which differ either chemically or mechanically.

Nature and Composition of Steel.—From the preceding definition it will be observed that the grand structural characteristic of steel, to which it largely owes its value for all

uses, is homogeneity due to fusion; also, that its chemical constituents and the characters due to them are very various. The important chemical qualities of tool-steel are: (1) The tempering quality, which is due, first, to the presence of say $\frac{1}{2}$ to $1\frac{1}{2}$ per cent. of carbon; second, to the mechanical mixture of this carbon with the metal by means of slow cooling from a red heat, which makes the metal comparatively soft, so that it can be cut with the ordinary tools; third, the extreme hardening of the metal, when, by means of sudden cooling, the carbon is chemically dissolved in the iron. (2) An important condition of tool-steel is its freedom from ingredients, such as phosphorus, which induce brittleness. Excepting some modern steels, in the manufacture of which nickel, manganese, tungsten, chromium, titanium, and some other metalloids are employed, the best tool-steels have but a few hundredths of 1 per cent. of any ingredient except carbon, silicon, and iron.

The more important qualities of structural steels vary with their precise uses. In general, great resistance to static strains, or to those gradually applied, is accompanied by comparative brittleness and unfitness to resist strains suddenly applied. High resistance, resilience, hardness, and brittleness increase, up to certain limits, with the amount of impurities, chiefly carbon, contained in the metal. Low resistance, softness, ductility, and toughness become more marked, within certain limits, as the impurities become less; but too little as well as too much impurity makes steel weak and unsuitable for structural purposes. It requires what is called body to give it resistance to either static or sudden strains. This body is imparted by carbon, manganese, silicon, phosphorus, and by other ingredients; but too much of either of them, or of certain compounds of them, weakens the metal. While it is known, generally, that the substances mentioned may to a certain extent replace one another as body-giving elements, and that some of them appear to neutralize others (for instance, that manganese restores the ductility of steel made brittle by phosphorus), comparatively little progress has yet been made in definite and formulated knowledge regarding the mechanical effects of chemical mixture in iron and steel.

The Manufacture of Steel.—(1) *The Crucible Steel Process.*—This is the oldest and simplest. It at first consisted in melting wrought iron with carbon in clay crucibles. Thus Indian "wootz" is made, containing as much as $1\frac{1}{2}$ per cent. of carbon, so that it requires decarburization before it can be forged. In the present manufacture other ingredients besides carbon, chiefly manganese, are added. Sometimes substances intended to combine with and remove the impurities in the wrought iron are introduced, but generally these impurities remain in the steel. The finest steel must therefore be made from wrought iron which has been purified by reworking with pure fuel, and which was originally made from pure ores. The melting-point of wrought iron is so high that it has been usual to carburize it by cementation (see FURNACE) in order to fuse it at a convenient temperature in crucibles. This cemented or blistered bar was the steel of commerce until Huntsman melted it in a crucible in 1770, producing a true cast steel. The use of the Siemens furnace and the modern improvement of crucibles render the melting of wrought iron practicable and cheap. The cheaper grades of crucible steel are largely made from Bessemer steel rail-ends, crop-ends, and other scrap. This material, being made directly from cast iron, without that purification from silicon and phosphorus to which wrought iron could have been subjected in puddling, produces an inferior steel to that made from the purest wrought iron for purposes, like tool-steel, requiring both hardness and toughness. By melting wrought iron and a little cast iron together, especially cast iron containing manganese, the cheaper grades of steel are produced. The impurities of the cast iron remain in the steel. Although crucible steel has been cheapened by using the materials mentioned, and by means of the gas-furnace, the less refined grades of steel are made at so much less cost and with so much greater uniformity by the open-hearth process, and within certain limits by the Bessemer process, that the crucible process is becoming gradually confined to the finer grades of tool-steel; and here it must probably long retain its superiority, chiefly because it can begin with a highly refined iron, from which especially phosphorus, silicon, and sulphur have been more or less completely eliminated.

The quantity of steel made by the crucible process is relatively small. The two processes which produce the bulk of the metal for rails, structural material, wire, nails, plates,

bogies, the plates, etc., are the open-hearth or Siemens-Martin process and the Bessemer process. Until the invention of Thomas and Gilchrist the only raw material available for these processes was such as contained only a small quantity of phosphorus, 0.10 per cent, being the limit for pig iron. Since all of the phosphorus in cast-iron goes into the iron produced in the blast furnace, this restricted the steel-maker in his selection of ores and pig iron. Thomas and Gilchrist ascertained that if there is substituted for the usual silica or "acid" lining of the Bessemer converter or open-hearth furnace a refractory lining consisting of a mixture of calcium silicate and bar, or of magnesia, a high phosphorus charge can be used. These latter linings are called "basic," in contrast with the older "acid" linings. Since their introduction it is the usual practice to distinguish between the "acid" and the "basic" open-hearth processes and the "acid" and "basic" Bessemer processes. The principal distinction in the two lies in the use of raw material, which must be low in phosphorus in the case of the acid process, and may or must be high in phosphorus in the case of the basic process. In the open-hearth furnace appliances are practically the same in either, the only difference being that the lime additions lead to the handling of a larger quantity of slag. In the basic Bessemer process the pig iron used must conform to certain specifications as to chemical contents. Silicon must be low, so that the life of the lining is not abridged by fluxing away in contact with the silica formed. From 14 to 2 per cent. of phosphorus is necessary in the basic Bessemer pig, so that its combustion during the blowing may furnish the necessary heat. Lime additions must be made, and the charging equally of the vessel is reduced through the room occupied by the greater amount of slag made. This slag is ground to an impalpable powder, and as such is used in agriculture as a substitute for phosphates, an important industry having been thus established.

(2) *The Open-hearth (or Siemens-Martin) Process.*—The melting of the ingredients of cast steel in large quantities and simply on the open hearth of a reverberatory furnace, rather than in small quantities and expensively in crucibles, having been often unsuccessfully attempted, was patented in a more scientific form by the eminent metallurgist Heath in 1845, and was then experimentally carried out with limited success. The Siemens regenerative gas-furnace, by means of the intensity and uniformity of its heat, first furnished practical conditions to the open-hearth process about 1862. It was also demonstrated by Messrs. Martin that the addition of manganese at a certain stage was necessary in the production of sound and practically malleable steel. The Siemens open-hearth steel furnace and its operation are fully exhibited and described under *FRASER*. The hearth or bed of the furnace consists of a shallow iron tank, ventilated below to prevent the concentrated heat of the hearth and the regenerators from endangering the structure, and lined with a very refractory material, usually silica, nearly pure, and just fusible enough to set into a solid mass. The red-hot air and gas, entering and burning at, say, the right-hand end of the furnace, play upon the materials placed on the hearth, and pass down into the regenerators at the left end, where they give off their heat to a checkerwork of brick-ticks. The current being reversed after some thirty minutes, the air and gas enter at the left end through the newly heated regenerators and pass out at the right end.

The design of furnaces undergoes some modifications when natural gas is used as a fuel, the Lusk furnace being the type most widely adopted in the U. S. An important modification of the ordinary open-hearth furnace has been introduced by H. H. Campbell, of Steelton, Pa., who has placed the entire hearth on rollers, which permit of tilting the furnace. This presents important advantages in charging and in tapping the charge. A plant of six of these furnaces, working 30-ton charges, is in operation at the works of the Pennsylvania Steel Company, three being basic and three acid furnaces.

The materials employed are various, and consequently the process varies, although the decarburization of pig iron is always a part of it. In order to obtain a sufficiently intense oxidation there must be a slight vacuum of air; the flame is therefore oxidizing, and would seriously waste wrought iron or the ingredients usually melted in crucibles. A bath of cast iron, which on account of its carbon can be melted without serious loss, is first necessary; in this is immersed and protected the more readily oxidizable materials for the production of steel. The amount of cast iron

varies from 10 to 25 per cent. of the total charge. For fine steels it should be as small as possible, so as to introduce the least amount of phosphorus, silicon, etc.

The more common process is known as the scrap process, and this again is divided into (1) the fusion of pig and scrap wrought iron or steel charged together, the former melting while the latter is heated preparatory to melting; (2) the dissolving of either hot or cold scrap in a bath of pig previously melted; (3) the dissolving of wrought iron sponge in a cast-iron bath. The operation in all these cases is chiefly the melting of the decarburized iron forming the bulk of the charge and the oxidation of the greater part of the carbon and silicon in the waste cast iron, and also in the basic process of the phosphorus. A portion of the iron is also oxidized, and this oxide of iron makes the product un-malleable or red-short. To remove the oxygen something must be added which has a greater affinity for it than iron has; for instance, manganese. The latter is easily and cheaply introduced in the form of pig iron called "spiegel-eisen," which contains 10 to 20 per cent. of manganese, or of an artificial ferro-manganese containing as high as 80 per cent. By using an excess of manganese any desired proportion of it remains in the steel. If the decarburization of the cast iron and the dilution of the carburized and uncarburized portions of the charge are carried only to such an extent that a highly carburized product remains, less manganese is needed to make it malleable, and this may be supplied by melting a manganese-rich pig iron with the charge. Dissolving scrap in the bath is the most common process; the scrap is fed to a little at a time, so as not to chill the charge and cause it to set on the bottom of the furnace, and also to maintain uniformity in the temperature and working of the furnace. To save part of the stress on the steel furnace, an auxiliary furnace is employed in some works to heat the scrap and spiegel-eisen before charging them into the bath.

In the production of boilerplate and of steels to be subjected to blows and vibration while in tension, for which the open-hearth process is largely used and well adapted, about 20 per cent. of the best Bessemer pig, containing less than 0.10 per cent. of phosphorus, and preferably not over 1 per cent. of silicon, is employed, the remainder of the charge being charged blooms made from Bessemer iron, or puddle-iron made by the boiling process, so as to free it as much as possible from phosphorus. For cheap steels, especially those in which hardness without great resistance to impact are required, a less pure pig and any wrought-iron scrap, such as old rails, may be employed. The phosphorus imparted by the latter may be rendered harmless by employing a rich ferro-manganese at the close of the process, thus adding a large amount (4 to 1 per cent.) of manganese and only 0.10 to 0.15 per cent. of carbon.

To ascertain when the charge is so far completed as to be ready for the manganese, samples are dipped out of the bath and tested from time to time. The decarburization is accurately denoted by the lengthness of the sample and by the appearance of its fracture. As soon as the manganese is thoroughly diffused through the bath the charge is tapped out and cast. In many cases the manganese is added to the charge after it has been tapped into the ladle. The open-hearth furnace is made to hold from 10 to 50 tons, the more usual capacity being from 20 to 25 tons. The time of the operation is from eight to eleven hours.

The pig-and-ore process, as developed by Siemens, consists in decarburizing a bath of pig iron by iron ore, and then adding ferro-manganese in the usual manner. The iron in the ore is added to the bath and a little limestone is thrown in to facilitate its separation. The theory is to use ore enough to make good the waste of the iron by oxidation. Although pig and ore may be employed alone with success, there is usually 10 or 15 per cent. of scrap made in rolling and forging, and this scrap is returned to the steel furnace. Sometimes 25 per cent. of scrap is added. The process thus partially takes the character of the pig-and-scrap process, although the use of ore as a rapid decarburizer of the large amount of pig employed gives it a distinctive character. The pig and scrap are first melted, the time being four or five hours. During this period an inch or more of slag forms over the bath. Then the ore is lumps up to 3 or 4 inches in diameter, is charged a little at a time until the bath is nearly ready for the manganese, when it is allowed to stand so that the iron may work out of the ore and slag. After the charging of the ore begins there are two distinct periods: First, the rising of the slag. This increases in weight, but much more in volume, and is covered with large

and heavily moving blotches or bubbles. Second, the boiling of the metal, when the slag settles and becomes thinner and the whole surface of the bath is covered with a lively spouting of the metal and slag, sometimes of the metal through the slag. These periods represent the following operations: (1) The silicon in the pig, having at this temperature a higher affinity for oxygen than the carbon has, is burned out first, partly by the flame, which is somewhat oxidizing, and partly by the oxygen in the ore. Thus slag is rapidly formed and also thickened by the release of the silica and other impurities in the ore. (2) When the silicon of the pig is nearly consumed its carbon begins to burn freely and to throw off carbonic oxide, which makes the now hotter and thinner slag boil violently.

(3) *Bessemer Process.*—The chemical part of the Bessemer process may be generally stated as the oxidation by means of air-blasts of the carbon and silicon (in the acid) or of the carbon and phosphorus (in the basic) in melted crude cast iron so as to make it malleable. During this reaction a certain quantity of iron is also oxidized. This is reduced by adding manganese pig iron, which reintroduces the necessary amount of carbon and also adds manganese, whose presence is useful in the subsequent rolling of the steel.

The Bessemer process as first performed, and as still practiced to a very limited extent abroad with irons rich in manganese, consists in applying the blast until all but one-fourth to one-half of 1 per cent. of the carbon is burned out, and then casting the product. Stopping the blast at this point, however, is very uncertain; hardly any irons contain the right amount of manganese for this treatment and the process has certain mechanical objections. Hence the nearly universal practice is to blow the iron until all the carbon is exhausted—a point readily determined; but the product now, as in the open-hearth process before described, contains so much oxide of iron that it is red-short and crumbles in working. To reduce this oxide of iron, manganese, which has a stronger affinity for the oxygen than the iron has, is added by running into the converter melted spiegeleisen, which is a pig iron containing 10 to 20 per cent. of manganese, or by otherwise adding ferro-manganese to the charge. Any desired amounts of carbon and manganese are also thus added to the product. No phosphorus is removed from the iron in the acid Bessemer process. Only the carbon and the silicon are oxidized. It is therefore important to start with pig irons having a little less phosphorus, sulphur, and copper than the steel may safely contain; but it is not usually practicable to use irons low in silicon, for the oxidation of this element produces the high temperature necessary to keep the mass fluid. Manganese is to a certain extent a substitute for silicon in this respect, and always a valuable ingredient, but the greater part of the irons of the world do not contain it in important quantities. Usually a pig containing from $1\frac{1}{4}$ to $2\frac{1}{4}$ per cent. of silicon is required. This will heat the charge to such a degree that 10 to 15 per cent. of scrap may be worked with the pig-iron charge. If there is more silicon than this the charge becomes too hot. One reason why silicon has greater heating power than carbon (it is stated by Akerman to have nine times as much) is because the product of its combustion, slag, remains in the converter, while the product of the combustion of carbon goes out in gaseous form, and carries much heat with it.

A standard American Bessemer plant of a type to which many existing works belong consists (1) of a melting department. The furnace and working-floor are shown in plan by Fig. 1; sections of these floors and the furnaces are shown by Fig. 2. There are hoists at *a* for coal, etc., and at *b* for iron; four cupola furnaces and their platforms and blowing machinery; two ladles, *K*, standing on scales, for weighing the melted iron; and spouts, *M*, *N*, Fig. 2, for conducting it to the vessels or converters; two reverberatory furnaces for spiegeleisen, and their spouts. (2) The converting department, shown in ground plan by Fig. 1 and in cross-section by Fig. 2. It contains two 5-ton to 7-ton vessels, *N*, in which the melted iron is treated by air-blasts. Such a vessel is illustrated by Fig. 3. Also a ladle and a hydraulic ladle-crane at *E*, Fig. 1, by means of which the steel is received from the vessels and poured into the ingot-moulds, which stand upon a depressed part of the floor called the pit. Three other hydraulic cranes swing over the pit to set the ingot-moulds and remove and load the ingots. Two of them swing over the vessels to assist in their daily repairs. The water and air pressure reservoirs are surmounted by a platform *d*, Fig. 1, standing upon which boys, by turning valves, admit water to the cranes and air to the vessels by

means of underground pipes. All the constant operations of hoisting, lowering, and blowing are conducted from this platform, which overlooks the entire converting department. (3) The engine department, which is not illustrated. It

FIG. 2.

FIG. 1.

contains a blowing-engine, usually a double engine, capable of delivering air at 25 lb. pressure per square inch. The water-pressure machinery for actuating the hydraulic machinery consists of a pair of duplex pumps.

The recent tendency in the U. S. has been to do away with the troublesome casting-pit. In one conspicuous case this is accomplished by pouring the steel into a ladle suspended from an overhead traveling crane. The steel is poured into moulds standing on cars, constituting a train, so that the whole charge can be hauled out of the converting-house by a locomotive soon after it is cast.

A growing practice in Europe and in the U. S. is to dispense entirely with the remelting of the pig iron in cupolas. The molten pig iron as it is tapped from the blast furnace is run into ladles mounted on cars. It is cast into a large vessel holding 100 to 150 tons of molten metal, called the mixer. From this mixer the iron is tapped whenever required, and in the quantities needed, into ladle-cars, from which it is poured into the converters direct. This is called the direct process.

In the older process, the pig iron, having been hoisted to the charging platform, is put, with, say, 10 per cent. of coal, into one of the cupolas and melted. When some 18,000 to 30,000 lb. (whatever charge is determined on) have run into one of the ladles, *K*, the latter is turned over by means of a worm-wheel, thus pouring the iron into the spout, which leads it to one of the vessels, the simplest form of which is shown in Fig. 3. A vessel that will convert a 6-ton charge is 8½ feet in external diameter and 15 feet high. It is made chiefly of ¼-inch to ½-inch iron plates, and lined nearly a foot thick with refractory material. At one end it has an 18-inch opening, called the nose; at the other a tuyere-box, communicating with the blowing-engine. From the tuyere-box 12 fire-brick tuyeres, each perforated with 12 ⅜-inch holes, project through and are imbedded in the lining. A tuyere is shown in section by *A*. These tuyeres last but 10 or 15 heats, and are arranged in such a manner as to be readily renewed. The vessel is mounted on trunnions, and turned by a hydraulic cylinder by means of a rack and pinion. When the charge enters for the process the tuyeres are turned up as at *C*, so that the iron will not run into

them. The blast is then admitted, and the tuyeres turned down so that the metal will flow over them, and be pierced by the entering columns of air. The cubical contents of the vessel is eight to twelve times that of the charge of iron.

FIG. 3.

in order to give room for ebullition. The vessel lining is heated red hot and the fuel discharged before the iron is turned in. The iron is now subjected to 144 streams of air, three-eighths of an inch in diameter, at 15 to 25 lb. pressure, for about twenty minutes. Most of the silicon is first burned out, the result being slag, and a comparatively dull flame at the converter-mouth. When the carbon begins to burn freely the volume and brilliancy of the flame increase; and as the surging mass grows hotter, and boils over in splashes of fluid slag, the discharge is a thick, white, roaring blaze, and the massive vessel and its iron foundations tremble under the violent ebullition. Toward the close of the operation the flame becomes thinner, and it suddenly contracts and loses illuminating power when decarburization is complete. The determination of this period is the critical point of the process. Ten seconds too much or too little blowing injures or spoils the product. At the proper instant, as determined best by the spectroscope or by colored glasses, but usually by the naked eye, the foreman turns down the vessel and shuts off the blast. The charge of spiegeleisen is then run in, when another flaming reaction occurs. The vessel being still further depressed, the steel runs into the ladle, pure, white, and shining, from under its coating of red-hot slag. A blanket of slag, most useful in preserving its temperature, follows it into the ladle. The metal is then let into the ingot-moulds and, after the exterior surface of the steel has crystallized, the mould is removed, and the ingot is ready for reheating and rolling.

For the basic process the converter is lined with a mixture of highly calcined dolomite (magnesian limestone) and tar, either by ramming it into place or building it up of brick made from the mixture. A certain amount of calcined lime is charged with the iron, further additions being made as required. When the carbon has been blown out, the slag is poured off and a brief period of blowing, called the after-blow, follows, during which the last portions of the phosphorus in the metal are eliminated, passing into the slag.

The ladle-crane (Fig. 4) is a radical departure from the nearest kindred practice. The ladle, instead of swinging from a crane-chain, as in a foundry, is rigidly held in a fixed orbit. This feature was original with Bessemer, and to it he added the old ladle with a pouring-nozzle in its bottom, regulated by a movable stopper (1 and 2). This consists of a loam-coated rod, *a*, armed at its lower end with a round-ended fire-brick or plumbago stopper fitted to the concave top of a fire-brick nozzle. The stopper is raised and lowered by a lever, *o*, in the hand of the workman. Thus the heavy steel is discharged pure, while the lighter slag and impurities are left at the top. Pouring steel into moulds over the rim of a ladle, as in foundries, would make excessive scrap from spilling and chilling, and is wholly impracticable. The vertical motion of the crane is necessary in pouring from the vessel, to keep the ladle close under the nose, thus preventing too great a fall of the stream, and consequent slopping. The ladle is also tipped by a worm and worm-wheel, *h*, to regulate the position of the nozzle over the moulds and to turn over the ladle for heating and repairs. The hydraulic crane generally used in works in the U. S. is also illustrated by Fig. 4, and consists of a cylinder open at the top only, and requiring chiefly vertical support from the solid pier on which it rests. The ram passes through an upper stuffing-box and through a top support in the roof of the building. The jib is placed between these supports, so that the lateral strain on the ram is comparatively small. The ram is stepped upon a column of water which is substantially frictionless.

When the steel is intended for rails—and sometimes 33 per cent. of that made in the U. S. is so used—the charges are so regulated as to cast either five or six ingots, and a little over as a margin for chilling and spilling. Each ingot

FIG. 4.

makes three or six rails. The ingots are removed hot to the blooming-mill, and if any heating-furnace is ready, they are charged into it directly, thus saving much heat. They must be allowed to crystallize, however, before rolling. If the interior of an ingot is still pasty from the heat of conversion, it will go to pieces in the rolls. Ingot for three to six rails each are used, instead of ingots for single rails—first, to save a repetition of manipulations in working. This must be done by machinery to be done cheaply, and a machine can handle a big ingot as quickly as a little one. Second, the extreme top of an ingot is unsound, and must be cut off and reconverted; the number of scrap ends is reduced to two for three to six rails. The practice is growing in the direction of large ingots and large reductions for all purposes; and the counterpart of this—to cheapen cost—is handling by steam and reducing rapidly by heavier rolls and hammers. See also ROLLING-MILLS.

Since about 1870 open-hearth and Bessemer steel have practically displaced puddled iron in the manufacture of rails, wire, plates, structural shapes, tin plate, and cut nails, and has made heavy inroads into its field, in bars and other shapes.

The production of crucible steel in the U. S. was 72,586 gross tons in 1891, 84,709 tons in 1892, and 63,613 gross tons in 1893. The production of open-hearth steel was 579,753 tons in 1891, 669,889 tons in 1892, and 737,890 tons in 1893. The production of Bessemer steel was 3,247,417 tons in 1891, 4,168,435 tons in 1892, 3,215,686 tons in 1893, and 3,579,101 tons in 1894.

The total production of basic steel in the world was 3,638,556 tons in 1893, Germany contributing thereto 2,344,754 tons. Of the total productions of basic steel in the world in 1893, 2,808,241 tons was Bessemer and 830,315 tons was open-hearth steel.

Great Britain produced in 1893 1,493,354 gross tons of Bessemer steel ingots and 1,456,309 tons of open-hearth steel ingots. Germany made 2,171,138 metric tons of manufactured steel in 1893. Belgium produced 273,058 metric tons of steel ingots in 1893; France produced 814,977 metric tons of ingots in the same year; Sweden has a record of 82,422 tons of Bessemer and 76,556 tons of open-hearth steel ingots in 1892; and Austria reports 509,734 metric tons of Bessemer and open-hearth ingots in the same year. The production of Russia in 1892 was 365,484 metric tons. Spain made

78,413 metric tons in 1891, and Italy 56,543 metric tons in 1892. A small quantity of steel is also produced in Canada.

Steele, DANIEL, A. M., D. D.: minister and educator; b. at Windham, N. Y., Oct. 5, 1824; educated at Wesleyan Academy and Wesleyan University, where he graduated 1848; joined the New England Conference of the Methodist Episcopal Church 1849; was pastor until 1862; Professor of Ancient Languages 1862-69 and acting president of Genesee College 1869-71; and vice-president of Syracuse University 1871-72; since then has taught in school of theology of Boston University, and served in several pastorates. He has published *Commentary on Joshua* (1872); *Binney's Theological Compend Improved* (1874); *Love Enthroned* (1875); *Milestone Papers* (1878); *Antinomianism Revived, or a Refutation of the Doctrines of the Plymouth Brethren* (1885); *Commentary on Leviticus and Numbers* (1891); *Bible Readings* (1892); *Sermons and Essays* (1892). ALBERT OSBOEN.

Steele, DAVID, D. D.: clergyman and professor; b. near Londonderry, Ireland, Oct. 20, 1827; educated at Miami University and the Theological Seminary of the Reformed Presbyterian Church, Philadelphia; principal of Cynthia Academy, Kentucky, 1857-58; Professor of Hebrew and Greek in Miami University 1858-59; pastor of the Fourth Reformed church, Philadelphia, since 1861; Professor of Hebrew, Greek, and Pastoral Theology 1863-75, and since 1875 of Doctrinal Theology in the Reformed Presbyterian Seminary, Philadelphia; was moderator of the General Synod 1868; delegate to the Pan-Presbyterian Council at Philadelphia 1880; president of the board of foreign missions in the Reformed Presbyterian church since 1883. Dr. Steele edited *The Reformed Presbyterian Advocate* 1867-77; and has published *The Times in which we live and the Ministry which they require* (1872); *Biographical Sketch of Rev. J. N. McLeod, D. D.* (1875); *The Apologetics of History* (1886); and discourses. C. K. HOYT.

Steele, FREDERICK: soldier; b. at Delhi, N. Y., Jan. 14, 1819; graduated at the U. S. Military Academy July 1, 1843, and was assigned to the Second Infantry; fought in the war with Mexico, gaining the brevets of first lieutenant and captain for Contreras and Chapultepec; served in California 1849-55, and on the Western frontier from 1855 until the outbreak of the civil war, when, as major of the Eleventh Infantry, he was engaged in Missouri, commanding a brigade in the actions at Dug Spring, Wilson's Creek, and retreat to Rolla. Appointed colonel Eighth Iowa Volunteers in Sept., 1861, and commissioned brigadier-general of volunteers Jan. 29, 1862, he commanded a division in the army of the Southwest until November, when promoted to be major-general of volunteers and assigned to the Thirteenth Army-corps, which he led in the Yazoo expedition and capture of Arkansas Post (Dec., 1862-Jan., 1863); transferred to the Fifteenth Corps, he was engaged in the Vicksburg campaign, when his division was sent to Helena, Ark., and captured Little Rock Sept. 10; in 1864 commanded the department of Arkansas, and on Nov. 29, 1864, went to the aid of Gen. Canby in the reduction of Mobile; was mustered out of volunteer service in Mar., 1867. For the capture of Little Rock he was breveted brigadier-general, and for meritorious services major-general U. S. army. In July, 1866, he was assigned to the colonelcy of the Twentieth Infantry, which he held at the time of his death, at San Mateo, Cal., Jan. 12, 1868.

Revised by JAMES MERCUR.

Steele, Sir RICHARD: author; b. in Dublin, Mar., 1672; educated at the Charterhouse, London, and at Oxford. In 1695 he enlisted as a private in the Life Guards, and in the same year published *The Procession*, a poem on Queen Mary's funeral. This was dedicated to Lord Cutts, who gave Steele a captaincy in his regiment, the Coldstream Guards. In 1701 he published *The Christian Hero*, a short manual of religious ethics, and in November or December of the same year brought out at Drury Lane his first comedy, *The Funeral*. This was followed by *The Lying Lover* (1703) and *The Tender Husband* (1705). About this time he became a member of the famous Kit-Cat Club, and married a widow, a Mrs. Margaret Stretch, who seems to have died in 1706. In May, 1707, through the influence of Arthur Maynwaring, he was appointed to the Government office of gazetteer. In Sept., 1707, he married Miss Mary Scurlock, of Llangun-

nor, Carmarthenshire, Wales. His letters to this lady were first printed in 1787. He was always in pecuniary difficulties; but such was his amiability that he always found friends to assist him, and was successively appointed to lucrative offices, among which were commissioner of the stamp office, surveyor of the royal stables, governor of the royal comedians, justice of the peace for Middlesex, and commissioner of forfeited estates in Scotland. In politics he was an ardent Whig. In 1713 he was returned to Parliament for Stockbridge, and was expelled in the following year on account of political articles written by him, but was knighted by the king, and returned to Parliament for Boroughbridge in 1715. In 1720 his patent as governor of the royal comedians was revoked, by which, according to his own statement, he suffered a loss of £10,000, and in the following year he brought out his successful comedy of *The Conscious Lovers*, which was dedicated to the king, who sent him a present of £500. His first wife, who died soon after their marriage, brought him a plantation in the West Indies, and his second wife was a Welsh heiress, but he squandered his large income in dissipation and unprofitable speculations, and being attacked with a paralytic stroke, which disabled him from literary work, he retired to his estate at Llangunnor, where he died Sept. 1, 1729. He was buried in St. Peter's church, Carmarthen. Several of Steele's political essays and pamphlets had a high reputation in their day, and his comedies were well received upon the stage. His chief fame rests upon his connection with *The Tatler* and *The Spectator*, almost the earliest of that long series of periodical works which occupy so prominent a place in English literature, although in these his part was much inferior to that of Addison, who had been his school-fellow at the Charterhouse. *The Tatler* (1709-11) contained 271 numbers; 188 were by Steele, 42 by Addison, and 36 by both conjointly. This was succeeded by *The Spectator* (1711-12), containing 555 numbers, of which 236 were by Steele and 274 by Addison. After the discontinuance of *The Spectator*, Steele, with the co-operation of Addison, started *The Guardian*, but Addison soon withdrew, and the work was brought to a close with the 176th number, of which 82 were by Steele. Steele started other papers, *The Englishman*, *The Lover*, *The Reader*, *The Theater*, and *The Spinster*, which were comparative failures; and he left two unfinished comedies, *The School of Action* and *The Gentleman*. His *Poetical Miscellanies*, original and translated (1714), possesses little merit. See *Memoirs of the Life and Writings of Sir Richard Steele*, by H. R. Montgomery (London, 1865), and *The Life of Steele*, by Geo. A. Aitken (2 vols., Boston, 1889). Also *Richard Steele*, by Austin Dobson (1886), who published his *Selected Works* in 1845.

Steeleyard, or Roman Balance: See WEIGHING-SCALES.

Steen, Jans, painter; b. at Leyden about 1690; a pupil of Nicolaes Knipfer at Utrecht, and afterward, at The Hague, of Jan van Goyen, whose daughter became his wife. In 1648 Jan Steen entered the corporation of painters at Leyden. He was absent from his native city for ten years, following it is said, the trade of a brewer at Delft; returned to Leyden in 1658 and continued the work of painter with that of tavern-keeper. He died at Leyden in 1679, and was buried Feb. 3. His work shows the influence of Frans Hals and Adrian van Ostade. His works are chiefly to be seen in the public and private collections in Holland. One example of his art, *The Music-master*, is in the National Gallery, London.

W. J. STILLMAN.

Steenskrup, Johannes, JONAHAS JAKOBUS SMITH; zoologist; b. at Vang, Norway, Mar. 8, 1813; Professor of Zoology at the University of Copenhagen until 1883. His principal works, which are characterized by elegance of style as well as originality of thought, are *Om Fjerskuldning og Udvaldt, gjenom valende Generationsordelse* (Copenhagen, 1842; translated from the German version as *On the Alterations of Generations* (1845); *Undersøgelser over Homophobidismens Tilværelse i Naturen* (Investigations in the Presence of Homophobidism in Nature, Copenhagen, 1846); and *Om Bille paa Naturen og Oldforskningens Betydning* (A Glance at Previous Studies of Nature and Archaeology, Copenhagen, 1862).

D. K. DUNN.

Steenwyck, Adriaen, ADRIANUS; architectural painter; b. at Steenwyck, in the province of Overijssel, Netherlands, about 1550; studied under Hans Vredeman de Brice; also at Antwerp in 1577, and then went in 1580 to Frankfurt-on-the-Main, where he died in 1608. His son, named Hendrick, also an architectural painter, was born at Frankfurt in 1580, both painted interiors of churches, halls, and rooms. The younger Steenwyck worked in Antwerp, but went in 1629 to London, where Van Dyke employed him to paint architectural backgrounds to some of his portraits. D. in London about 1649. The Louvre, the Belvedere at Vienna, and the National Gallery at London contain examples of the art of father and son. Herman Steenwyck, of Delft, and his brother Pieter are not to be confounded with the above mentioned—these were painters of still life.

W. J. S.

Steeple-chase: See HORSE-RACING.

Steevens, Thomas, SHAKESPEARE scholar; b. at Stepney, London, May 10, 1756; was educated at King's College, Cambridge; devoted himself to Shakespearean studies, and in 1786 published, in 4 vols. 8vo, *Twenty of the Plays of Shakespeare, being the whole number printed in Quarto during his lifetime*, etc., which led to his association with Dr. Johnson in an annotated edition published in 1773 under their joint names. Afterward, in conjunction with Isaac Reed, he prepared two new editions (1785 and 1793). His editions remained the standard for the text for almost fifty years. He also assisted in the preparation of the *Biographia Dramatica*, and furnished contributions to Nichols's *Biographical Anecdotes of Myerth*. D. at Hampstead, Jan. 22, 1800.

Revised by H. A. REES.

Steiffens, Henrik; philosopher; b. at Stavanger, Norway, May 2, 1773; educated in Denmark 1779-84, and studied theology and natural science at the University of Copenhagen; went in 1794 to Germany, and became, through the study of Schelling's writings and through personal intercourse with the author, a zealous adept of the new sensational science, the so-called philosophy of nature. He returned to Denmark (1802), where he exercised a decisive influence on his contemporaries. His principal works from this period are *Revisionen von Schellings naturphilosophischen Schriften* (1800); *Grundzüge der philosophischen Naturwissenschaft* (1800); *Anthropologie* (2 vols., 1822); and *Philosophie der Natur zur Beförderung der speculativen Physik* (1823-25). He continued his study of mineralogy and geology at Freiberg under Werner (*Geognostisch-physikalische Aufzeichnungen* (1810) and *Handbuch der Oryktognomie* (3 vols., 1811-19); was appointed Professor of Natural Science in 1804 at Halle, in 1811 at Breslau, and in 1831 at Berlin. D. in Berlin, Feb. 18, 1845. In religion he first turned from the stiff orthodoxy in which he was educated to the platform of Spinoza, which he found at Halle; then he became an ardent proponent among the Old Lutherans at Breslau; and finally,

at Berlin, he adopted Schleiermacher's religion of the feeling (*Von der jüdischen Theologie und dem jüdischen Glauben* (1824); *Wie ich wieder Lutheraner wurde und wie mir das Lutherthum ist* (1831)). He was also the author of several novels of a marked didactic character. His autobiography, *Was ich erlebte* (10 vols., 1840-45), was translated into English by William L. Gage under the title *The Story of my Career as Student at Freiberg and Jena* (Boston, 1861), and republished under the title *German University Life* (Philadelphia, 1874); *Nachgelassene Schriften* (1846), with a preface by Schelling). Revised by D. K. DUNN.

Steganocephalus [Mod. Lat., pl. of *steganocephalus*; Gr. *stegano*, covered, well covered; *cephalus*, head] an order of birds containing those which have all four toes connected with a web; synonymous with *Tidipalmidae*. It contains the gulls (*Scelopidae*), pelicans (*Pelecanidae*), cormorants (*Phalacrocoracidae*), darters (*Pelecanidae*), frigate-birds (*Fregatidae*), and tropic-birds (*Phaethonidae*). It is the equivalent of Huxley's *Diogenes-morphus*. See the articles on the various genera. F. A. L.

Steganocephala [Mod. Lat., Gr. *stegano*, covered + *cephala*, head] a group of extinct batrachians, like the salamanders in general appearance, but differing from all recent forms in the well-developed armor of bony plates which covered the skull and which usually extended over the lower surface of the body, and sometimes also covered the back. They first appeared in the Carboniferous and died out with the Triassic age. Some were small, others were veritable giants. The group is interesting to the naturalist since its affinities are apparently with the ganoids, and at the same time it is the ancestor of the batrachians of to-day.

J. S. K.

Stein, Otto, HERMANN FRIEDRICH KANT, HERRMANN; statesman; b. at Nassau-on-the-Lahn, Oct. 26, 1757; studied jurisprudence at Göttingen 1775-77; entered the civil service of the Prussian Government in 1780, and was made chief of the department of commerce, manufactures, and indirect taxation in 1804. Strongly opposed to the policy adopted by the president of the cabinet, Count Haugwitz, and by the king himself, he was dismissed Jan. 4, 1807, but recalled immediately after the Peace of Tilsit (July 20, 1807), and made president of the cabinet. In this position he developed an astonishing energy. His internal reforms were a complete reorganization of the Prussian state; Serfdom was abolished, and universal obligation of military service introduced; the material estates of the nobility were taxed, all citizens made equal before the law, a liberal municipal system established, and on the crown lands the system of peasant proprietorship was introduced. His final aim was to elevate the peasant class and to create a powerful and intelligent middle class, and, with the nation reorganized on this basis, to renew the contest with Napoleon. He had also a clear idea of what a united Germany meant, and was adverse to that division of the country into petty states which had given the history of the nation such a chaotic and anarchical aspect. But his career was suddenly stopped. An insidious letter, in which he criticised the policy of Napoleon and spoke of his own hopes and plans, fell into the hands of the French police, and was published in the *Moniteur* Sept. 8, 1806. On Nov. 24 Stein was compelled to resign, and on Dec. 16 Napoleon sent a decree from Madrid which outlawed him and confiscated his property. He went to Austria, thence to Russia, but once again he was at the head of the political affairs of Germany during the period between Napoleon's disaster in Russia and the Peace of Paris, when he actually was the leader of the diplomatic coalition against France. After peace had been concluded, his influence soon became comparatively small. The German princes hated him for his ideas of a German unity; the absolutists hated him for his ideas of a representative form of government; and he himself was unwilling to adopt the impracticable views of the radicals. He retired to his estate, and died at Kappenberg, Westphalia, June 29, 1851. Monuments have been erected to him in Nassau and in Berlin. See the biography by Perle, and Sadler's *Life and Times of Stein* (1879, 3 vols.). See also the *Erinnerungen von Heyn* (1891). Collections of his letters have been published, and are of great importance for the history of that time.

Revised by F. M. COLBY.

Stein'bok [from Dutch *steenhok*, and Germ. *steinbock*; *stein*, stone + *bok*, antelope]; any one of several species of the family *Bovidae*. (1) The German designation *Steinhock* (and hence the Dutch *steenhok*) was originally conferred on the ibex or bouquetin of Europe, a species of goat, and to that animal the name properly belongs. (See BOUVETIN.)

(2) The Dutch settlers of Southern Africa applied the name to a species of antelope peculiar to and not uncommon in that region, and it is now incorporated in the English vocabulary of animals in connection with it. The species is the *Nanotragus tragulus* (*Pediotragus campestris* of Gray). The steinbok is an animal of graceful and symmetrical form, with the head well proportioned, having a bovine nose and large muffle; the horns, developed only in the male and over the orbit, erect, elongate, and subulate; the legs long and slender; the feet destitute of side-hooflets; and the tail very short. The color is a fulvous ash above and on the sides, and white beneath. The length is generally rather less than 3½ feet, and the height at the shoulder somewhat more than 1½ feet. The species is most abundant on stony plains and in valleys, and especially on open flats, where large stones and clumps of trees are found. It is very swift, and progresses by great bounds. It is also very timid, and readily alarmed. It is much esteemed for its flesh.

THEODORE GILL.

Steinen, KARL, von den: ethnologist and traveler; b. at Mülheim-on-the-Ruhr, Prussia, Mar. 7, 1855. He studied medicine at Zurich, Bonn, and Strassburg, and ethnology at Berlin and Vienna; made a voyage round the world 1878-81, and was artist and naturalist attached to the German expedition to the Antarctic island of South Georgia 1882-83. In 1884-85, with two companions and a detail of Brazilian soldiers, he penetrated the unknown regions of Northern Matto Grosso, Brazil, discovered the head waters of the river Xingú, and descended it to the Amazon. A second journey to the upper Xingú was made in 1887-88. Dr. von den Steinen's works include *Durch Central-Brasilien* (1886), describing the first Xingú exploration; *Unter den Naturvölkern Central-Brasilien* (1894); and many scientific papers.

HERBERT H. SMITH.

Steinhell, LOUIS CHARLES AUGUSTE: genre, still-life, and portrait painter; b. in Strassburg, June 26, 1814; d. in Paris May 17, 1885; pupil of Decaisne; third-class medals, Salons, 1847 and 1851; second-class 1848; Legion of Honor 1860. His *Mother* (1847) is in the museum at Nantes.

Steinmetz, KARL FRIEDRICH, von: b. at Eisenach, Saxe-Weimar, Dec. 27, 1796; entered the Prussian army in 1813 as a lieutenant; fought against the French; became a captain in the regiment of Kaiser Franz in 1829; fought at the head of two battalions of the Second Infantry Regiment in Mar., 1848, in the streets of Berlin; was subsequently made governor of the academy of cadets at Berlin, and made his name illustrious as commander-in-chief of the Fifth Army-corps in the campaign against Austria in 1866. On June 27, 28, and 29, 1866, he made a stand at Nachod, Skalitz, and Schweinschädel with his corps and one brigade against three corps of the enemy, defeated them, drove them back, and took eleven guns and 6,000 prisoners. By this victory he made it possible for the second army to debouch, on which maneuver the success of the Prussian battle-plan depended. He received immediately the highest order, that of the Black Eagle, and the Diet voted him a national dotation. In the war against France in 1870 he was appointed commander-in-chief of the First Army, consisting of the First, Seventh, and Eighth Army-corps, but he held this position only for a short time, as he came in conflict with the supreme command—in what manner is not exactly known, but it seems as if the advance of the First Army on Aug. 6, and the measures taken by the general during the advance toward and around Metz on Aug. 14, 15, and 16, did not agree with the plans of von Moltke. In reality, the general now lost his independent command, his army being united to that of Prince Friedrich Charles, and the supreme command given to the prince. Nominally, however, Steinmetz remained a commander, subject only to the orders of the king, and thereby, as well as from the stubbornness of his character, arose disagreements between him and the prince. The result was that in Sept., 1870, Steinmetz was appointed governor-general of Posen and Silesia, and removed from the theater of war. He handed in his resignation, which, however, the king did not accept. He was made a general-field-marshal Apr. 8, 1871, and placed *à la suite*. D. at Landeck, Prussian Silesia, Aug. 4, 1877.

Stein'schneider, MORITZ: bibliographer; b. at Prossnitz, Moravia, Mar. 30, 1816; studied in Prossnitz, Nikolsburg, Prague, Vienna, Leipzig, and Berlin; teacher in Prague 1842; teacher in Berlin 1845; since 1859 director of the Veitel-Heine-Ephraimsche Stiftung in that city, and from 1869 to 1890 head of the Israelitische Töchter-Schule. He

received the degree of LL. D. from Columbia College 1887; the title of professor 1894. He has devoted himself especially to the non-theological literature of the Jews and Arabs during the Middle Ages. As a bibliographer and historian of Hebrew literature he is unsurpassed. Among his numerous works are *Catal. libr. hebr. in bibl. Bodleiana* (Berlin, 1852-60); catalogues of the Hebrew MSS. in the libraries of Leyden (1858), Munich (1875), Hamburg (1878), and Berlin (1878); *Jewish Literature* (London, 1857; *Index*, Frankfurt, 1893); *Zur Pseudepigraph. Lit.* (Berlin, 1869); *Alfarabi* (Petersburg, 1869); *Polem. und Apologet. Lit.* (Leipzig, 1877); *Bibliograph. Handbuch* (Leipzig, 1859); and *Hebräische Uebersetz. des Mittelalters* (2 vols., Berlin, 1893), a work which received the prize of the Académie des Inscriptions in Paris. See Berliner, *Die Schriften des Dr. M. Stein'schneider* (Berlin, 1886). RICHARD GOTTHEIL.

Steinthal: See OBERLIN, JOHANN FRIEDRICH.

Stellarton, formerly ALBION MINES: town of Pictou County, Nova Scotia; 3 miles from New Glasgow and 39 miles N. E. of Truro, on the Intercolonial Railway (see map of Quebec, etc., ref. 2-C). It is a thriving but dingy town which has grown up about the Albion coal and iron mines, the center of the chief mining district of the province. Petrolium is obtained in the vicinity. The town is the chief destination of the French immigrants to the province. Pop. (1881) 2,297; (1891) 2,410. M. W. H.

Steller's: a group of echinoderms, including the STAR-FISH (*Asteroides*) and (OPHIUROIDEA (*qq. v.*), in which the body is star-shaped.

Stellhorn, FREDERICK WILLIAM: theologian; b. in the kingdom of Hanover, Germany, Oct. 2, 1841. Emigrated to the U. S. in 1854; graduated at the institutions at Fort Wayne, Ind., and St. Louis, Mo.; pastor in St. Louis and DeKalb co., Ind., 1865-69; Professor of Hebrew, Greek, and Latin, Northwestern University, Watertown, Wis., 1869-74, and in Concordia College, Fort Wayne, 1874-81; since 1881 has been Professor of Theology, Capitol University, Columbus, O. In the Predestination controversy he parted from the Missourians and entered the Joint Synod of Ohio. He has been active as editor of the *Theologische Zeitblätter* and *Lutherische Kirchenzeitung*, as well as a contributor to *The Theological Magazine*. He has published a *Lexicon of New Testament Greek* (Leipzig, 1886), and begun a commentary on the New Testament, of which the volume on the Gospels has appeared. H. E. JACOBS.

Stellio [Lat. *stellio*, a newt with starlike spots on its back, deriv. of *stella*, star]: a genus of lizards of the family *Agamidae*. The best-known species is *S. cordylina* of the Levant. Strict Mohammedans kill it because they conceive that by the frequent bowing of the head it intends to insult their religion, mocking their own gestures at prayer. The Turks use its flesh and excrement in preparing a cosmetic.

Stem [O. Eng. *stenn*; Germ. *stamm*, a deriv. of Indo-Europ. root *stā-*, stand, and originally denoting the trunk of a tree]: a term of historical grammar denoting that part of a word which is left when the inflexional ending is removed. The stem may therefore be identical with the root; e. g. in Lat. *vōx*, Gr. *ῥῶξ*, or, in the Gr. verb *ἐλ-μ*, but the stem is more commonly formed by adding to the root a formative element called a suffix. Thus in Indo-Europ. *klutis* = Sanskr. *grutās*; Gr. *κλυτός*; Lat. *in-clutus*, *s* is inflexional ending, *kluto-* is stem, *clu-* is root, and *-to-* is suffix. Similarly we divide *φῦγ-ός*, *fūg-u-s*; *γῆν-ός*, *tōm-u-s*, *unc-u-s*, *dol-u-s*; *ἔγ-ω-s*, *stud-iu-m*; *τέκ-ν-ος*, *grā-nu-m*; *πῶ-τι-s*, *cu-ti-s*; *αἰχ-ῆ-α*, *hom-in-em*; Sanskr. *jān-as-as*, Gr. *γῆν-ε(σ)-ος*, Lat. *gen-er-is*, etc. The relation of stem to root in the verb is evidently parallel to that in the noun—an inheritance from a period prior to the development of a grammatical distinction between noun and verb; thus the *φερ-*, *φερο-* of *φέρει-ται*, *φέρονται* is to the *εσ-* of *εσ-τι*, or the *ει-* of *ει-σι* as the *λογο-* of *λόγος* is to the *φλεβ-* of *φλέψ*. Though the purposes of grammatical analysis are well served by this division of stem into root and suffix, it by no means follows that in every case the suffix was an originally independent word or element. On the contrary, the form of the stems is in many cases due to the influence of analogy, and in others to the retention of the fuller original form of the primitive word which has elsewhere suffered reduction by the loss of a vowel. (See Root.) The word stem as thus used in grammar is a translation or transfer of the German word *stamm*, meaning the trunk (of a tree) in distinction to the *wurzel* or root.

BENJ. IDE WHEELER.

Sten'dal: town and railway junction; in the province of Saxony, Prussia; on the Elbe; 36 miles by rail N. by R. of Magdeburg (see map of German Empire, ref. 4-E). It has a Gothic cathedral, manufactures leather, tobacco, woollen, linen, and cotton stuffs, and trades in corn and cattle. Pop. (1890) 16,473.

Stenoglossa [from Gr. *stenos*, slender + *glossa*, tongue]: a group of molluscs, embracing the *Rhachiglossa* and *Turloglossa* of the *Gastropoda*, in which the lingual ribbon is narrow.

Stenog'raphy [from Gr. *stenos*, narrow, close + *graphein*, write]: a generic term which embraces every system of shorthand writing, whether upon alphabetic, phonetic, or hieroglyphic principles. To those systems which are based upon the phonetic principle is given the name *phonography*; which therefore indicates a species of stenography. Some of the other names under which new stenographic systems have been introduced are *tachygraphy* (swift writing), *brachygraphy* (short writing), *semigraphy* (sign writing—that is, writing with signs), *cryptography* (secret writing), *ideography*, *zeigigraphy*, *polygraphy* (writing much—that is, voluminous writing), *radiography* (easy writing), and *thygraphy* (swift writing).

Stenography among the Greeks.—The great need of some method of representing in legible characters spoken words as fast as uttered was appreciated in the earliest times, and traces of shorthand writing may be found among the Greeks not many centuries later than the introduction and diffusion of the art of writing. The conclusion has been arrived at that among the Greeks Xenophon was the inventor of stenography, some method of which he employed in recording the *Memorabilia* of Socrates. Many references show that some style of writing briefer than that in common use was known at this time, though it is not clear that use was made of characters not found in the common alphabet. It has been suggested that certain references in the Bible to "ready writers" (Ps. xiv. 1) show that some system of brief writing was known to the Hebrews, but the passages relied upon to establish the proposition have only suggestive force.

Stenography among the Romans.—Among the Romans it is probable that the first efforts at brief writing were reflected in the representation of certain frequently recurring words by contractions in the ordinary spelling, as by their initial letters; thus: R. P. for *Res Publica*, P. R. for *Populus Romanus*, S. P. Q. R. for *Senatus Populusque Romanus*. The next step was the representation of certain frequently recurring terminations of words by arbitrary contractions or signs; and the next, the representation by arbitrary characters of words and phrases. Etruscan the poet is said to have invented and used (239-169 B.C.) a series of 1,100 arbitrary characters for the ready representation of words. The first attempt at any system of stenographic writing is variously attributed to Cicero and to his freedman Tiro. Certain it is that Tiro, by the use of a system which he had mastered if not invented (and which is said to have been improved by Macer), took down and thus secured the preservation of Cato's great oration against the proceedings of Caesar respecting the Catilinarian conspiracy, as well as Cicero's own orations respecting the same. Julius Caesar, Augustus, and Titus Vespasian are said to have been proficient in the art of shorthand writing; and this is clearly shown by many references in Horace, Ovid, and other writers. The following is an illustration of the Tironian system:

Tironian Notes.

Translation.

Quem posthūmū sūper dūm iūstū & ratiōnabīlīb; dīvīnū mīserīcōrdīā fāvēmū, & rāz eorū lōī adīstōrīo

Stenography among the French.—There are said to be still extant, in the characters of the Tironian system, an inventory and fifty-four charters of Louis the Pious, successor of Charlemagne, copies of which were republished at Paris in 1747; but, whatever use was made of stenography during the Middle Ages, few traces are found of it previous to the end of the eighteenth century. The first

work of importance to herald the revival of the art was an adaptation of Taylor's (English) system (1792) by Theodore Pierre Bortin. Since then half a dozen systems have been published, among which is that of Fayet, *Nouvelle Ecriture de Stenographie* (1832), but those in use by most of the practical reporters (1895) are the systems of Dupuy, de Prépeau, Aimé-Paris, and Guélin.

Stenography among the Germans.—The credit of the first introduction of shorthand into Germany (1606) is given to one Marhof. His system was rapidly followed by others. The systems generally in use are those of Gutschmager (1831) and Stolze, which have the merit of possessing to a great degree the slant of ordinary writing and the inclusion of many sharp angles, giving easy joinings, and distinguishing often by light and shaded characters.

Stenography in Great Britain.—Probably in no other nation have so many systems of shorthand been put forth as in England. The earliest of any prominence was that of Timothy Bright (London, 1588)—*Character, or Art of Short, Swift, and Secret Writing by Character*. Two years later appeared the system of Peter Dales, under the curious title *The Writing Schoolmaster, in three parts*. The more prominent of the succeeding systems were those of Willis (1602), Rich (1654-60), Mason (1672), republished with improvements by Gurney in 1753. Byrnes published his first work in 1739, and his universal English shorthand in 1767. Taylor's book appeared in 1792, Lewis's in 1815, and Harding's in 1823. Harding's system was an adaptation of Taylor, and Isaac Pitman was induced to take up shorthand by seeing this book. Between the publication of Bright's work in 1588 and Selwyn's in 1847, about eighty different textbooks appeared, nearly all of them of unphonetic systems. Isaac Pitman's system appeared in 1837. It was based upon phonetic principles; and, by reason of the simplicity of its consonants, and its copyright protection, made rapid strides in public use. He made use of Harding's pairing of the consonants and Good's use of hooks. Notwithstanding the general popularity of Pitman in England, the larger number of the legal and parliamentary official writers use (1895), with more or less modifications, the older systems, especially Gurney, Taylor, and Lewis. For his long and devoted service in advancing the phonographic art, Isaac Pitman was knighted in 1894.

Stenography in the United States.—Only a few purely stenographic systems have received even temporary encouragement in the U. S., and this is due to the striking superiority of such as have found favor as well as to their comparative earliness in the field. The first system introduced was that of Keyes A. Bayley (New York, 1831). This was followed by several American editions of Isaac Pitman's (English) system, by Andrews and Bayley, Booth, Paterson, and Benn Pitman (1853). Day and Statton brought out an unphonetic system in 1836, Thomas Townsend a phonetic one in 1837, and Charles Saxton an unphonetic one in 1842. Lindsey's tachygraphy (which is slow, and has the feature of writing in the vowels, and the merit of linearity) was introduced in 1854. Andrew J. Graham's adaptation was introduced in 1858, and rapidly found favor. The author undertook to provide a means of securing greater brevity by omissions, combinations, extended word and phrase signs, half-lengths, ticks, and other devices; and while many of his modifications and innovations were regarded as exceedingly valuable as time-savers, numerous practical writers believed that he had carried his ideas of abbreviation too far, and that a strict application of his system would result in the sacrifice of legibility to brevity. From the date of his first *Handbook of Standard Phonography* till his death in 1894 he published a large number of text-books and readers. Munson's system (introduced in 1890) is founded on that of Isaac Pitman, and has received a considerable degree of support. Its distinguishing features are the inversion of the original Pitman vowel scale and the use of small initial hooks on curved strokes for R and large ones for L, thereby avoiding the turning of a curved stroke for L and R hook, as in Fr, Vr, Thr, etc. Bishop (1887) employs a system of connectible, well-distinguished stroke vowels, treated in analogy with the treatment of the consonants, and claimed to give greater exactness and facility in representing any sound whatever used in speech, and to simplify the sciences by leaving less to mere memorizing and more to the application of fundamental principles. Other systems in the U. S. are Ogensby's and Burns's, both of which are adaptations from Pitman with considerable variations, the former exceedingly brief, and the latter being successfully prac-

ticed and taught by its author; and Longley's, a phonetic system. It is believed that Graham's modifications are used by more official court stenographers in the U. S. than all other adaptations of Pitman. The Bann Pitman, Graham, and Munson systems are probably more generally taught than any others, and each has a comprehensive dictionary.

Shorthand writers are employed as official reporters in both branches of Congress, in all the State Legislatures, and in nearly every important court in the country. Few newspapers now employ them for shorthand work alone, usually hiring an expert writer whenever a verbatim report of a lecture, sermon, trial, or other proceeding is wanted. The art of shorthand writing has become an invaluable promoter of general business activity, and has opened up a pleasant field of work for young men and young women. There is a constant demand for those possessing a knowledge of shorthand writing and a facility with the typewriter.

The more prominent systems in use in Germany, France, Great Britain, and the U. S. have proved equal, in the hands of experts, to the task of keeping pace with the most fervid oratory; but it must be acknowledged that the requirements of the art are so arduous that only those who have devoted years to the practice, and are, withal, specially adapted for the work, can ever hope to make themselves equal to the highest exactions of the profession. See PHONOGRAPHY.

Revised by THEO. C. ROSE.

Steph'anus, or Stephens (Fr. *Estienne* or *Étienne*): a family of French printers, several of whom were also noted as scholars. HENRY STEPHENS, the founder of the house (b. about 1460; d. in 1520), established himself in 1502 as a printer in Paris, where his works became famous for the accuracy and beauty of their typography. He was aided, and afterward succeeded in business, by his three sons, the most distinguished of whom was his second son ROBERT (b. in Paris, 1503), who was eminent as a scholar, and in 1531 began the publication of his great *Dictionarium, seu Thesaurus Linguae Latinae*, of which he put forth three editions, the last in 1545, and which has been several times republished. He also published editions of the Bible, with notes which were censured by the Sorbonne because of their Protestantism, and indeed Stephens was a Protestant, but he was protected by Francis I., who had made him royal printer. After the death of the king the Sorbonne prohibited the sale of his Bibles, and he was obliged to take refuge in Geneva, 1551, where he continued printing and died Sept. 7, 1559. He published nearly a dozen complete editions of the Bible in Hebrew, Greek, Latin, and French, and numerous separate editions of the New Testament in various languages, besides many other very important works. The present division of the New Testament into verses was made by him and first introduced in his Greek-Latin Testament published at Geneva 1551. After he had taken refuge in Geneva, the business in Paris was conducted by his brother CHARLES (b. 1504; d. 1564), who was appointed printer to Henry II., and put forth numerous classical and scientific works.—HENRY, son of Robert (b. 1528; d. Mar., 1598), was especially eminent as a Greek scholar, and carried on his business at first in Paris, and afterward in Geneva. He almost ruined himself financially by the publication of his *Plato* (1578) and his immense *Thesaurus Linguae Graecae* (1572, 5 vols. fol., reprinted with additions, London (by Valpy), 1815–28, and again, Paris (by Didot), 9 vols. fol., 1831–65), for at that time Greek students were too few in number to afford purchasers for an edition. He subsequently traveled from place to place, visiting all the principal libraries, for the purpose of collecting materials for various works, which he procured to be

printed by others. Among these works is his *La Précellence du Langage françois* (1579).—PAUL, the son of Henry (b. 1566; d. 1627), carried on the printing business at Geneva for many years.—ANTHONY, the son of Paul (b. 1592; d. 1674), removed from Geneva to Paris, where for nearly half a century he conducted a printing-house, but with ultimate ill success. He died at the Hôtel-Dieu in Paris in utter destitution, and with him was extinguished this line of famous scholars and printers.

Revised by S. M. JACKSON.

Stephen, SAINT [*Stephen* is from Lat. *Stēphanus* = Gr. *Στέφανος*, liter., crown]: the first of all Christian martyrs. He was one of the seven deacons in the Christian congregation of Jerusalem. Charged by the Jews with speaking against the law and against God, he was stoned to death by order of the Sanhedrin. His history is given in chapters vi. and vii. of the Acts of the Apostles. His festival is held on Dec. 26, both in the Eastern and Western Churches.

Stephen I., SAINT: King of Hungary. See HUNGARY (*History*).

Stephen: the name of ten popes. Some historians, however, count but nine, from the circumstance that Stephen II. died three days after his election, Mar. 27, 752, before he had been consecrated. The following bearers of the name are the most noteworthy: STEPHEN I., Saint: pope from about 254 to 257 A. D.; is noted for his controversy with Cyprian as to the necessity of rebaptizing converted heretics. The councils of Carthage (255 and 256) having decided against the Roman practice of recognizing baptism by heretics as valid, Stephen broke off communion with the African Church.—STEPHEN III. (II.): pope from 752 to 757; suffered severely from the aggressions of the Lombards. After asking in vain for help against them from the Byzantine emperor, Constantine Copronymus, he went in person to Pepin le Bref, chief of the Franks, whom he crowned king on the condition that he should expel Aistulf, the Lombard king, from the exarchate of Ravenna and the Pentapolis and bestow these territories on the see of St. Peter. Pepin made two campaigns in Italy, but succeeded at last in forcing the Lombards to retreat from the above territories, which he then gave to the papal see, in spite of the protest of the Byzantine emperor, thereby laying the foundation of the temporal power of the pope.—STEPHEN VII. (VI.) (896–897) is most noticeable for his violence in respect to his predecessor Formosus, whose corpse he caused to be exhumed, stripped of the papal insignia, mutilated, and thrown into the Tiber, at the same time annulling all his ordinances, and even his consecrations.—STEPHEN X. (IX.) (1057–58) was a son of the Duke Gotelon of Lower Lorraine, and was elected pope through the influence of Cardinal Hildebrand, afterward Pope Gregory VII., who was the real master of the Church.

Stephen: King of England; b. in Normandy about 1100: son of Stephen, Count of Blois, by Adela, daughter of William the Conqueror. William, the only son of Henry I., was drowned in 1120, and the heir-presumptive to the crown was his daughter Matilda, who was married to Henry V., Emperor of Germany; but before the death of her father the emperor died, and she married Geoffrey Plantagenet, Earl of Anjou, without the royal sanction, which was held to invalidate her right to the succession. Upon the death of Henry I. (in 1135), Stephen claimed the succession, although he was not next in the line, even if Matilda was set aside, for he had an elder brother, Theobald, Count of Blois; he was, however, chosen by a party of the prelates and nobles, and his election was sanctioned by the pope. At first his government was fairly successful. He ingratiated the English by issuing a charter confirming the favorable laws of Henry I.'s reign. He made peace with the Scots, whose king, David, paid him homage, and when the war broke out again the English were victorious in the battle of the Standard. The entire reign, however, was filled with revolts and civil war. The cause of Matilda was taken up by a party in England, headed by her natural brother, Robert, Earl of Gloucester, and after a contest of several years Stephen was defeated and made prisoner at Lincoln Feb. 2, 1141. The rule of the empress was so unpopular that a revolt broke out, and her brother, the Earl of Gloucester, was defeated and captured, but was afterward exchanged for Stephen. The civil war now raged with varying fortunes for ten years. In 1153 Prince Henry Plantagenet, son of Matilda, arrived in England at the head of a considerable force; but before a decisive action took place, the barons on both sides entered upon an armistice, and finally concluded the treaty of Wallingford by which Stephen should retain the crown during his

life, and that after his death Henry should succeed him. Stephen survived this treaty only a few months, and with him ended the line of Anglo-Norman Kings of England. D. Oct. 23, 1154.

Stephen, Henry Jones; jurist; cousin of Sir James and Sir George Stephen; b. in England in 1787; was called to the bar at the Inner Temple 1818; became commissioner of bankruptcy; was a distinguished practitioner at the London bar, and became sergeant-at-law 1827. D. at Clifton, Nov. 28, 1864. Author of a *Treatise on the Principles of Pleading in Civil Actions* (1824; 8th American ed., Philadelphia, 1836); of a *Summary of the Criminal Law in its present state* (1844); and of *New Commentaries on the Laws of England* (4 vols., London, 1841-45). In the preparation of three subsequent editions of this great work the author enjoyed the assistance of his son, James Stephen, LL.D.; b. in England in 1829; called to the bar at the Middle Temple 1846; became Professor of English Law and Jurisprudence at King's College, London; recorder of Poole, registrar of bankruptcy at Leeds, and circuit judge at Lincoln. He issued later revised editions of his father's *Commentaries*, also *Questions for the editions*, and was author of treatises on *Due Diligence* (1851) and *The Common-law Procedure Act* (1860). Revised by F. STURGES ALLEN.

Stephen, Sir James Fitzjames; jurist; b. at Kensington, London, Mar. 3, 1829; educated at Trinity College, Cambridge (B. A. 1852), and was called to the bar at the Inner Temple in 1854; traveled circuit, and became recorder of Newark-on-Trent 1859-68; succeeded Sir Henry J. S. Maine as legal member of the legislative council of India 1869; with the assistance of two others he drew up and passed through the council a code of criminal procedure, which, with considerable modifications, was re-enacted as the code of 1882; prepared, and finally passed, the Indian Evidence Act of 1872. He returned to England in 1872, where he undertook the codification of the English law of evidence (which he never completed), and of English substantive criminal law, the resulting code being reported too late for the code of 1879, and subsequently dropped from the Government measures; in Dec., 1875, was appointed Professor of Common Law by the Inns of Court, and a member of the council of legal education and law reporting; was made Knight Commander of the Star of India in 1877, and appointed a judge of the Queen's bench division, which office he retained until he was stricken with insanity in 1891. D. in London Mar. 11, 1894. He wrote besides his great work, *History of the Criminal Law of England* (which is far more than a mere legal treatise; 3 vols., 2vo., 1893), a *Digest of the Law of Evidence* (1876); *Essays of a Barrister* (1892); *Liberty, Equality, and Fraternity* (1873); *Digest of the Criminal Law* (1877); and many monographs on legal subjects. See *Law Times* (Mar., 1894). F. STURGES ALLEN.

Stephen, Leslie, LL.D.; author; b. at Kensington, London, Nov. 28, 1832; son of Sir James Stephen and brother of Sir James Fitzjames Stephen. He was educated at Eton, King's College, London, and Trinity Hall, Cambridge (B. A. 1854), of which last he was a fellow. In 1864 he went to London and engaged in literary pursuits; edited *The Cornhill Magazine* 1871-72, resigning to take charge of the important *Dictionary of National Biography*. The first twenty-six volumes of this (1885-91) were issued under his supervision, and he was then succeeded in the editorship by his collaborator, Sidney Lee. In 1889 he held the Clark lectureship on English literature at Cambridge. He married Harriet Marion, younger daughter of William M. Thackeray. Among his writings are *The Playground of Europe* (1871); *Free Thinking and Plain Speaking* (1873); *Hours in a Library* (1874-76); *History of English Thought in the Eighteenth Century* (1876); *The Science of Ethics* (1882); *An Apologist's Apology* (1896); besides biographies of Pope, Swift, Johnson, and Henry Fawcett, and an edition of *Poetical Works* in ten volumes (1892). H. A. REES.

Stephen Báthori, *Bathory*; King of Poland; b. in 1532 of a celebrated Hungarian family; was Prince of Transylvania, and in 1576, after Henry of Anjou's abandonment of the Polish throne, was elected King of Poland. He put the Jesuits at the head of the new university which he founded at Wilna, and gave them many other preferences, but their efforts to induce him to put down the Reformation in Poland were in vain. In military respects he was successful, and humiliated the Russians several times, forcing them out of Livonia, which was then reannexed to Poland. D. at Gdansk, Dec. 12, 1596.

Stephens; a family of French printers. See **STEFANUS**.

Stephens, Alexander Hamilton, LL.D.; statesman; b. near Crawfordsville, Ga., Feb. 11, 1812; graduated at the University of Georgia 1832; admitted to the bar 1834; entered upon political life 1836 as member for Tallapoosa of the State House of Representatives; was successively re-elected to the same office until 1840; declined an election 1841 (the next year was chosen State Senator by the same constituency). In 1843 he was elected member of the House of Representatives of the U. S. That office he occupied until 1850, when he voluntarily retired to private life. The compromise measure passed by the Congress of 1850 had no bolder, abler, or more eloquent champion than Stephens. He was chosen a delegate to the State convention of that year—the convention which established the celebrated "Georgia platform." In 1855 he united with the Democrats to defeat the Know-nothing party. In the presidential campaign of 1860 he was placed at the head of the Douglas-Johnson electoral ticket. He was a delegate to the State convention of 1861 which passed the ordinance of secession. That measure he earnestly opposed by speech and vote, but, while he advised against the policy of secession for existing grievances, he maintained the right of a State to secede peacefully from the Federal Union for sufficient cause. When a majority of the convention passed the ordinance of secession, he readily acquiesced in their decision. He was a member of the Confederate provisional congress; was chosen vice-president of the provisional government of the Confederate States; was appointed commissioner to the convention between their government and the State of Virginia; was elected by the people, without opposition, to the vice-presidency of the Confederacy under the permanent constitution, as it was styled; and, when in Feb., 1863, the fortunes of the Confederacy were desperate beyond the reach of hope, he was placed at the head of the commission on the part of the Confederate States government in the famous Hampton Roads conference. After the downfall of the Confederacy he was arrested and confined a prisoner of state in Fort Warren for five months; he was released on his own parole in Oct., 1865. In Feb., 1866, the General Assembly elected him, by a large majority, against his wishes, to the office of U. S. Senator, but Congress ignored the restoration of Georgia to the Union under the presidential proclamation of Andrew Johnson, and he was not allowed to take his seat in the Senate. He was elected to the 43d, 44th, 45th, 46th, and 47th Congresses, in each case without more than nominal opposition; inaugurated Governor of Georgia Nov. 4, 1882. He belonged to the Jeffersonian school of American politics, and among the cardinal articles of his political creed were State rights, State sovereignty, local self-government; he always advocated the largest liberty of the citizen compatible with the attainment of the two prime objects of government—viz., protection to property and preservation of order. He wrote a *Constitutional View of the War between the States* (3 vols., 1867-70); a *School History of the United States* (1870-71); and a *Compendium of the History of the United States* (New York, 1883). D. at Atlanta, Ga., Mar. 4, 1883.

Revised by C. K. ADAMS.

Stephens, Ann Sophia (Winterbotham); novelist; b. at Derby, Conn., in 1813; became the wife of Edward Stephens in 1841; soon after they went to Portland, Me., where in 1835-37 she edited *The Portland Magazine*, and in 1846 compiled *The Portland Sketch-book*, a volume composed of the writings of natives or residents of that city. In 1837 they removed to New York, her husband subsequently receiving an appointment in the custom-house. She edited and contributed to various periodicals, and wrote many tales and novels, and some fugitive poems. A uniform edition of her works has been issued (new ed. 23 vols., Philadelphia, 1896). Among her most successful novels are *Fashion and Famine* (New York, 1854); *The Old Homestead* (1855; 2 vols., Philadelphia, 1869); *Mary Deveret* (1860); *The Rejected Wife* (1863); *Silent Struggles* (1865); *Mabel's Mistake* (1866); *Wives and Widows* (1866); *Married in Haste* (1870); *The Reigning Belle* (1872); *Ballad and Bondage* (1875); and *Phemie's Experience* (1874). D. at Newport, R. I., Aug. 30, 1886. Revised by H. A. REES.

Stephens, Gossow; archaeologist; b. in Liverpool, England, Dec. 18, 1812. After spending several years in Stockholm he was in 1851 appointed acting Professor of the English Language and Literature at the University of Copenhagen, and four years later permanent professor; resigned in 1866. He has been several times decorated and is an

honorary member of a number of scientific societies. His chief work is *The Old Northern Runic Monuments of Scandinavia and England* (London and Copenhagen, 3 vols. fol., 1866-84). As a collection of plates and transcriptions, this work is invaluable, but many of the readings and criticisms have since been effectually disproved by Wimmer and others. He has also published a number of monographs and texts, English and Scandinavian, a translation of Tegnér's *Frithiof's Saga*, and a melodrama, *Revenge, or Woman's Love*.
D. K. DODGE.

Stephens, JOHN LLOYD: jurist, traveler, and author; b. at Shrewsbury, N. J., Nov. 28, 1805; graduated at Columbia College 1822; studied law and practiced in New York. In 1834-36 he traveled in Europe and the East; published *Egypt, Arabia Petraea, and the Holy Land* (2 vols., 1837), and *Greece, Turkey, Russia, and Poland* (2 vols., 1838). In 1839 President Van Buren appointed him special commissioner to negotiate a treaty with Central America. The civil war in that country prevented him from accomplishing his purpose; but in company with an English artist, Frederick Catherwood, he traveled in Central America and Southern Mexico, making a special study of the ancient ruined cities. Returning to New York he published *Incidents of Travel in Central America, Chiapas, and Yucatan* (2 vols., with fine illustrations by Catherwood, 1841). The results of a second journey, also with Mr. Catherwood, were embodied in *Incidents of Travel in Yucatan* (2 vols., 1843). These two works attained a wide circulation, and gave for the first time good popular descriptions of the wonderful Central American cities. Mr. Stephens was a delegate to the convention for revising the constitution of New York, 1846. In 1847 he took an active part in the organization of the first Atlantic steam-navigation company. After the discovery of gold in California he entered, with characteristic energy, into the scheme for a rail route across the Isthmus of Panama; was one of the first presidents of the Panama Railway Company, and personally superintended the construction. From exposure on the isthmus he contracted a disease of which he died in New York, Oct. 10, 1852.

HERBERT H. SMITH.

Stephens, WILLIAM: president of the colony of Georgia; b. on the Isle of Wight, England, Jan. 28, 1671, son of Sir William Stephens, lieutenant-governor of that island; graduated at Cambridge; studied law at the Middle Temple; sat in Parliament 1696-1722; settled at Charleston, S. C., about 1730; was appointed secretary of the colony of Georgia 1737; became president of the county of Savannah 1741, and governor of Georgia 1743-50. D. in Georgia in Aug., 1753. He was the author of *A Journal of the Proceedings in Georgia* (London, 3 vols., 1742). His biography was written by a son under the title of *The Castle-builder, or the History of William Stephens of the Isle of Wight* (2d ed. London, 1759).

Stephenson, GEORGE: engineer; b. at Wylam, Northumberland, England, June 9, 1781, the son of a poor colliery laborer. He was in childhood an engine-boy; became a fireman, and in time was placed in charge of an engine, which he studied until he had mastered its construction so as to be able to take it apart and put it together again. Accident gave him an opportunity of putting in motion a steam-engine which needed repairs, and in 1812 he was made engine-wright at Killingworth Colliery. The problem of constructing a locomotive steam-engine was then engaging many minds, and he was in 1814 the first to construct one which proved satisfactorily operative. He originated the steam-blast, which was introduced into his second locomotive, built in 1815, and in that year devised a miner's safety-lamp, for which a large prize had been offered by colliery-owners; but Sir Humphry Davy having simultaneously invented his safety-lamp, this prize, valued at £2,000, was awarded to him, £100 being awarded to Stephenson by the committee; a separate subscription of £1,000 was raised in 1817, which was presented to Stephenson, and his lamp is still in use in some English collieries. Stephenson then turned his attention to improvements in railways as well as engines. The first railway built by him, opened in 1822, 8 miles long, was so successful that in the next year he was appointed engineer of the railway authorized to be constructed between Stockton and Darlington, and in 1825 of the Liverpool and Manchester line, which was begun in 1826. He had in the meantime set up an establishment at Newcastle-upon-Tyne for the manufacture of locomotives, and on Oct. 6, 1829, his engine, named the Rocket, attained

an average speed of 14 miles an hour, and for a short distance was driven at the rate of 29 miles. (See RAILWAYS.) During the next fifteen years he was actively engaged as a railway engineer and contractor in England and on the Continent, still carrying on his great locomotive-factory at Newcastle, and also engaging in coal-mining and lime-works. He passed the closing years of his life at his seat, Tipton Park, Derbyshire. D. Aug. 12, 1848. He retained during all his life, in speech and manners, much of the rustic simplicity belonging to his early life, and declined the honor of knighthood. By common consent he has received the title of the father of railways, and in 1862 a colossal bronze statue was erected in his honor at Newcastle-upon-Tyne. See Smiles's *Life of George Stephenson* (1857; new ed. 1874).
Revised by R. H. THURSTON.

Stephenson, ROBERT: engineer; son of George Stephenson, engineer; b. at Willington Quay, near Newcastle-upon-Tyne, Oct. 16, 1803. He had little opportunity to obtain an education when a boy, and in 1819 he was apprenticed to a coal-viewer; but as his father's circumstances improved he gave his son the best education within his means, and in 1822 sent him to the University of Edinburgh, where he remained six months studying chemistry, mathematics, and geology, after which he assisted his father in railway surveying and in the locomotive-works at Newcastle. In 1824 he went to South America, where for three years he superintended the working of the Columbian Mining Association. He then returned to England, where he aided his father, partly in laying down the line of the Liverpool and Manchester Railway, but more especially in the locomotive-works; and to him chiefly belongs the honor of the practical development of the details of the locomotive and the railway. He was appointed engineer of the London and Birmingham Railway, which, built almost wholly under his direction, was opened in 1838, and from this time he was employed in similar undertakings at home and abroad. He constructed several of the most stupendous iron railway bridges in the world, including the high-level bridge crossing the Tyne at Newcastle, the viaduct over the valley of the Tweed at Berwick, the Conway tubular bridge, the Britannia tubular bridge crossing the Menai Straits, the Victoria tubular bridge over the St. Lawrence in Canada, and those crossing the Nile at Damietta, Egypt. In 1847 he was returned to Parliament for Whitby. He received the great gold medal of honor from the French Industrial Exposition of 1855, and was president of the Institute of Civil Engineers from 1855 to 1858. He published a *Description of the Locomotive Steam-engine* (1838); *Report on the Atmospheric Railway System* (1844); and *The Great Exhibition, its Palace and Contents* (1851). D. Oct. 12, 1859. He was buried in Westminster Abbey, where a memorial window has been placed to his memory. See Smiles's *Life of George Stephenson* (new ed. 1874), and *Life of Robert Stephenson*, by J. C. Jeaffreson and W. Pole (2 vols., 1864).
Revised by R. H. THURSTON.

Stepniak, SERGIUS MICHAEL DRAGONOFF: author; b. at Gadatch, government of Poltava, Russia, 1841; member of a semi-noble family descended from the Cossacks of Little Russia; studied at Kieff 1859-63; published in that time in the Little Russian dialect some works which were prohibited by the Government in 1862; became docent in ancient history in the University of Kieff 1865; professor 1870; removed from his chair 1873 by the Government; exiled in 1876 on account of his criticisms on the system pursued by Count Tolstoi, one of the Ministers of Justice; settled in Geneva 1877, and published a review, *Gromada*, in the Ukraine dialect; settled in London 1885. He has labored to establish equal political rights for all people in Russia, and has declared against socialism as well as absolutism. Among his principal works are *The Turks Within and Without* (Geneva, 1876); *La Russia Sotterranea* (Milan, 1881; Eng. trans. *Underground Russia*, 1883); *Russia under the Tsars* (Eng. trans. 1885); *Tyrannicide in Russia* (1881); *Historical Poland and the Muscovite Democracy* (1881); and *The Career of a Nihilist*, a novel (1889). He has contributed numerous papers to the magazines and reviews.
C. H. THURBER.

Steppe: the name given by the Tartars to the plains of Central Asia. They are usually covered with grass, and correspond in their aspects and relations to the prairies of the U. S. and the llanos and pampas of South America. See PLAIN.

Steppe-murRAIN: See RINDERPEST.

Sterculia'ceæ [Mod. Lat., named from *Sterculia*, the typical genus, from Lat. *Sterculus*, the patron deity of manuring, deriv. of *ster'cus*, dung]: a family of exogenous trees, shrubs, and herbs, mostly tropical. Many of the trees are of prodigious size, such as the baobabs and those of the genera *Bombax* and *Ceiba*. Many produce abundantly a substance called silk-cotton, which resembles true cotton, but will not spin well. The wood is often very light and soft. The family contains medicinal plants, and produces some excellent fruits, some gums, a few valuable bark-fibers, and a number of useful timber-trees; but its most important product is chocolate, from the oily seeds of *Theobroma cacao*. The flowers or fruits of certain species are putrid, whence the botanical name. Revised by L. H. BAILEY.

Stere: See METRIC SYSTEM.

Sterelmin'tha [Mod. Lat., Gr. *στερεός*, solid + *ἐλμιν*, *ελμινθος*, a worm]: a name given to some of the PLATHELMINTHES (q. v.), in allusion to the absence of all cavities in the body.

Stereo-chemistry: a branch of chemistry that has to deal with the relations which the atoms bear to one another in space. The ordinary methods of investigation of chemical compounds lead to certain conclusions in regard to the connections existing between the atoms in a molecule. Thus when water is expressed by the formula $H-O-H$, no attempt is made to tell anything about the arrangement in space of the two atoms of hydrogen and the atom of oxygen. The formula expresses the view that each of the two atoms of hydrogen is linked to the atom of oxygen, but the question whether they are on the same side or on opposite sides, above or below, is not touched. Yet it is certain that if these atoms exist and are united in the molecule they must be arranged in space, and a formula that does not take into consideration the three dimensions of space is certainly incomplete. Up to within a comparatively short time no facts were known that justified any speculation concerning the space-relations of atoms, but it appears that the time has come when such speculation is profitable, and facts are constantly being brought to light that can not be explained without its aid.

The investigations of Pasteur on the different varieties of tartaric acid form the basis of stereo-chemistry. Pasteur found that racemic acid, which can easily be made, can be converted into ordinary tartaric acid and a new variety of tartaric acid, and when these two varieties of tartaric acid are mixed in solution they form racemic acid. Ordinary tartaric acid, when examined with the aid of a polarizing apparatus (see POLARIZATION), is found to turn the plane of polarization to the right, while the new variety obtained by Pasteur turns the plane to the left, and racemic acid is optically inactive—that is to say, it has no effect on polarized light. No explanation of these facts was offered until many years later. Meanwhile other cases similar to that studied by Pasteur were discovered, and chemists came to see more and more clearly that their theory of chemical constitution required an extension in order to accommodate it to the facts. At about the same time, and independently, Van't Hoff and Le Bel made a suggestion with reference to these cases that has proved to be of great value. The main idea is this: The atom of carbon, which, as is well known, has the power to unite with four univalent atoms or groups, is supposed to exert its four affinities from a center toward the angles of a tetrahedron—that is, symmetrically in space. Suppose all four atoms or groups that are in combination with the carbon atom to be of one kind, then but one arrangement of them in space is possible. So also if three are of one kind and one different, or two of one kind and two of another, they can be arranged in but one way around the central carbon atom. When, however, all four atoms or groups are different, then two arrangements in space are possible. The difference between the two arrangements is that which is observed between either one and its reflection in a mirror. Imperfectly the two arrangements are shown in the accompanying figures, in which C represents the carbon atom

FIG. 1.

FIG. 2.

and R, R₁, R₂, and R₃ represent four different radicals or atoms.

A carbon atom which is thus in combination with four

different atoms or radicals is called an *asymmetrical carbon atom*. The proposition of Van't Hoff and Le Bel is that the presence of such an atom in a compound makes possible a kind of isomerism that is due to the arrangement of the constituents in space. In the case of the tartaric acids there are in fact two asymmetrical carbon atoms present. The constitution of these acids is represented by the formula

It will be seen that each of the two carbon atoms that are represented as being in combination with each other is asymmetrical, a fact that is more clearly brought out by writing the formula thus:

Accordingly, this compound presents the conditions necessary for the two arrangements in space—one right-handed, the other left-handed, corresponding to the action of the two varieties of tartaric acid on polarized light.

The same general statements hold true for the lactic acids, which are represented by the formula

There are two varieties of ordinary lactic acid which are apparently analogous to the two optically active varieties of tartaric acid, and, further, there is a third variety corresponding to racemic acid, and formed by the union of the two active varieties. The relations between the inactive racemic acid and the active tartaric acids, and between the inactive lactic acid and the two active varieties are not understood. It can only be said that in each case the molecule of the inactive substance must consist of at least one molecule of each of the two active varieties.

Investigation has shown that the asymmetrical carbon atom gives to the compounds in which it is present the property of optical activity and the power to form peculiar isomeric varieties which can not be accounted for by the ordinary theory of constitution. Much progress has been made of late years in the study of the phenomena of stereo-chemistry. Perhaps these phenomena are best illustrated in the field of the sugars, the remarkable studies of Emil Fischer in this field having led to the discovery of a large number of new sugars, the existence of which it appears to be impossible to explain without the aid of the principles of stereo-chemistry.

Werner and Hantzsch have extended the ideas of stereo-chemistry to some classes of compounds containing nitrogen, with interesting results.

IRA REMSEN.

Stereochrome: See FRESKO.

Stereoscope [from Gr. *στερεός*, solid + *σκοπεῖν*, to view]: an instrument to aid the eyes in obtaining binocular combination of two similar, or nearly similar, pictures. As long ago as the time of Euclid (B. C. 300) it was known that when a near object is regarded with both eyes the aspect is different to each eye separately. No practical application of this was made to the study of binocular vision until 1838, when Sir Charles Wheatstone constructed perspective drawings of a geometric solid as seen by each eye separately when held at a fixed distance in front of the face. The width of each drawing was made a little less than the distance between the pupils of the two eyes. In order that one of them should be seen only by the right eye and the other only by the left, Wheatstone looked through a pair of tubes; and the visual effect was found to be that of an apparently solid body in space. In order to obtain this effect more conveniently and to use larger pictures he constructed the first reflecting stereoscope. A pair of plane mirrors, *m p* and *m q* (Fig. 1), were fixed upon a frame at right angles to each other, one pair of edges being in contact at *m*. Light from the pictures, *a b* and *a' b'*, was reflected into the eyes, R and L, so that the combination appeared to be at A B.

Wheatstone's invention did not become popularized because of the difficulty of constructing accurate perspective drawings to use with it. If two such conjugate drawings be placed beside each other in the same plane, the corresponding edges, *a* and *a'* (Fig. 2), being on the right and representing one of the remoter points of the object pictured,

while c and c' represent one of the nearer points, it can be easily proved geometrically or ascertained by careful measurement that the interval between c and c' is and must be less than that between a and a' . The rays from c and c' after reflection appear to the eyes to have come from some point, C , nearer than A or B if the arrangement is such as to produce the least discomfort to the eyes. It was natural for Wheatstone to conclude that the localization of each point in the binocular field of view is determined by the intersection of the

FIG. 1.—Diagram of Wheatstone's stereoscope.

visual lines reflected into the eyes. This theory of binocular perspective was long held and is still frequently expressed or implied.

Prior to the invention of Wheatstone's stereoscope, James Eliot, of Edinburgh, constructed a pair of conjugate perspectives of a landscape, but not until 1839 did he construct an instrument for viewing it. This was merely a small box open at the two ends, with a partition along the middle, equivalent to a pair of tubes. About the same time the art of photography was introduced by Talbot and Daguerre. In 1849 Sir David Brewster improved upon Eliot's form of box stereoscope by putting at the eye end a pair of semi-lenses of glass with thin edges opposed. In connection with this he devised the double camera for taking photographically the pair of pictures composing the stereograph. The stereoscope and camera were carried by him to Paris during the following year. Here the stereo-

FIG. 2.

scope was popularized by Duboscq, who made these instruments and stereographs for it in great number and with various modifications.

The form of open stereoscope commonly in use in the U. S. was devised in 1861 by Dr. Oliver Wendell Holmes. In this the box is discarded, but the pair of semi-lenses is retained, being fixed at one end of a shaft on which slides the stereograph-holder.

If the pair of conjugate pictures be transposed, that originally intended for the right eye being put on the left, the effect is reversion of relief, foreground points appearing in the background. Without such transposition or use of the stereoscope the same result may be attained by muscular crossing of the visual lines. By relaxing the muscles of the eyeball the right eye may be directed to the right picture and the left eye to the left. The visual lines then may often become divergent, but the localization in the field of view is perfect. This fact disproves the theory of stereoscopic perspective held by Wheatstone and Brewster. The apparent distance and size of the binocular image are much affected by the degree of strain imposed upon the muscles which control the eyeballs and the crystalline lens. The object of the stereoscope is to attain the binocular image with the least possible disturbance of the conditions of natural binocular vision.

The bibliography of this subject is included in that of VISION.

W. LE CONTE STEVENS.

Stereotyping and Electrotyping [*stereotyping* is deriv. of *stereotype*, from Gr. *στερεός*, fixed + *τύπος*, impression, type]: the art or process of making metal plates, reproducing in facsimile the surface of engravings or type set up as for direct printing. Stereotypes are plates of type-metal of the same composition throughout; electrotypes have a facing, usually of copper, deposited by electricity.

I. STEREOTYPING.—Before the invention of stereotypes a work to be printed at intervals, as occasion demanded, had to be kept continually in type (at considerable risk of error creeping in) or else reset for each edition. About 1725 the plaster process of stereotyping was invented by William Ged, a goldsmith (b. in Edinburgh, 1690; d. 1749). In 1731 a company formed by Ged contracted with the University of

Cambridge to print Bibles and prayer-books by stereotype, but after the printing of two prayer-books the contract was abandoned, owing partly to the hostility of pressmen to the innovation. Ged returned to Edinburgh, and in 1736 completed an edition of Sallust, which was printed in 1744. Few other attempts at stereotyping were made till 1793, when William Carey, the missionary, devised the method of letting the form of type fall face downward on a surface of hot lead at the point of solidifying, and then repeating this process with the matrix so formed, the result being a true reproduction of the original form in stereotype. Firmin Didot, of Paris, modified this plan by using types of a harder alloy, (30 parts of lead, 80 antimony, 80 tin, and 10 copper); a form of such type was pressed into a surface of pure lead, and the matrix thus obtained was attached to the hammer of a stamping-press and brought down upon a roll of type-metal about to solidify, thus flattening it out and forming a stereotype plate suitable for printing.

The method of Herhan, another French printer, was to set up the form in copper matrices in intaglio and take a cast in type-metal therefrom, thus procuring a cameo impression at one operation.

Stereotyping was introduced into the U. S. by David Bruce, of New York, in 1813. The first work stereotyped in America was the New Testament in 1814. The process of curving stereotype plates to adapt them to a cylinder printing-press was patented in England by Cowper in 1815, but was not very successful till applied to the Hoe perfecting-press. There are three leading methods of stereotyping—plaster, clay, and papier-maché; but only the last-named is now much employed. The metal used approaches type-metal in composition, and the plates after being used may be remelted and the metal used again.

Plaster Process.—For this the type is set up with shoulder-high spaces and quadrats. The surface is thinly and evenly oiled with a brush and the form is then inclosed in a rectangular frame termed a flask. Plaster-of-Paris mixed with water is poured upon it, forming a mould corresponding to the face of the form. When this has sufficiently hardened it is withdrawn and dried in an oven until all the moisture is driven off. The mould, laid face downward upon a casting-plate (floating-plate), is then placed within a casting-tray, which has a lid with openings at the corners. The whole is heated to about 400° F. while suspended by a crane over a pot of molten metal, and then gently lowered into the bath until the metal just flows into the corner openings, forming a thin plate which fills up all the cavities in the face of the mould. After being immersed eight or ten minutes the tray is lifted out and lowered upon a stone so arranged that the face of the plate is cooled first, and as shrinkage takes place more metal is added. The pan is then opened and the cast is separated from the mould and fitted to a block so as to make it type-high for printing.

The Clay Process (or Clay-and-Plaster Process).—For this the form is locked up with high furniture and slugs and placed on the bed of a special press, the face of the type being brushed over with benzine or naphtha and covered with a cloth. A plate covered evenly to the depth of $\frac{1}{4}$ inch with a mixture of equal parts of ground French clay and plaster-of-Paris moistened to the consistency of mortar is turned down over the type, and a partial impression taken; then, after opening the press to remove the cloth and any surplus clay, a complete impression is taken, imbedding the type in the plastic material to the desired extent. The mould is then removed and hardened by drying, and after being heated to the temperature of molten metal is inclosed on three sides by an iron wire, to which, over the face of the mould, a sheet of metal is clamped, as in a moulder's flask. The metal is poured into the open edge, and after cooling the mould is removed from the cast by washing. Curved plates for the Hoe press were cast from moulds made by using on the press a sheet of steel of the desired curvature spread flat and carrying the clay on what was its concave side. After the impression was taken the sheet was released and resumed its normal curvature, bending the plastic mould with it. The finished stereotype appeared as if taken from a type a little more condensed one way than that actually employed.

The *papier-maché* process was invented by Genoux in 1829 and introduced into Great Britain by Wilson, of Scotland, in 1832. It is far more expeditious than any other (by Hoe machines in 1895 plates could be made in six minutes), the type used suffers no perceptible injury, curved plates can be made with the same facility as flat, and a large number

of plates can be used from the same matrix; this process has therefore been adapted by all large daily papers. The material for a paper-matrix matrix is formed by spreading paste over a sheet of moderately thick unsized paper and covering it with successive sheets of tissue-paper, each carefully rolled down smooth by means of a heavy iron roller. The whole is usually saturated with water, although some prefer using the matrix softened only by what moisture there is in the paste. The type matter is imposed in an ordinary chase and inclosed with type-high bearers, these having the inside top edge grooved out, making a bolster for the sheet of paper-matrix which is then laid upon it, tissue side next the type. The face of the type is sometimes slightly oiled, and the surface of the sheet treated with powdered French chalk, but this is found to be unnecessary in most kinds of newspaper work. If the work is done by hand in the old way a thin cloth is moistened and laid on the back of the sheet, which is then thoroughly beaten into the form with a stiff brush. Much better and quicker work is done by machinery, however. In this method the form, covered by the sheet and a blanket, travels backward and forward under a large roller, and is then conveyed to a drying-press, where it receives strong pressure while resting on a large chest filled with steam under pressure. The matrix thus becomes dry and hard very quickly, and as it is held under pressure during the process, there is none of the roughness or distortion often produced in one taken from the form in a partially soft condition. After being taken from the drying-press and removed from the form, the matrix is exposed for half a minute to a strong heat, either in an oven or the flame of a gas-jet, to expel any remaining moisture. The edges of the matrix are then trimmed, and it is placed face up on the bottom of a casting-box, flat or cylindrical according to the shape of the plates to be made. It is inclosed on three edges by the sides of the box, which are as high as the stereotype plate is to be thick, and the fourth edge, over which the metal is to be poured, is covered by a thin sheet of steel or old matrix to prevent metal running under the matrix; the lid of the box is then fastened down and molten metal is poured in at the uppermost open side, a two-handed ladle being usually employed in conveying it from the furnace. The plate is made considerably longer than the matrix at the open end in order to allow for the shrinkage as the metal cools. On being removed from the box this end is cut off, and the plate is trimmed and shaved down on the reverse side in order to bring it to the exact thickness required, all being very rapidly done by machinery.

The *chalk-plate process* is a method of producing drawings on plates to be used in a printing-press, and is similar in principle to stereotyping proper. A sheet of metal is covered thinly with a soft material, like chalk, about $\frac{1}{4}$ of an inch thick, and the drawing is transferred to this surface, after which the chalk is scraped away where the lines show, leaving the steel bare. The plate is then put in an ordinary casting-box, and used as a matrix. The cast is trimmed square, and made exactly type-high; it may then be locked in its place in the form, and treated just as an engraving, a paper-matrix being made from the whole.

II. ELECTROTYPING.—The method of producing casts by means of electricity, as explained in the article *ELECTROTYPE* (p. 73), is much employed in making plates for printing, especially from engravings and for bookwork, as electrotypes give a clearer impression and are more durable than stereotypes proper. A wax mould is first made from the engraving or type (set with shoulder-high spaces) and powdered graphite is spread over its surface so as to make it a conductor of electricity; copper may then be deposited on it by the ordinary process of electroplating. The first plates successfully used for printing were made by Joseph A. Adams, a wood-engraver of New York, who made casts from wood-cuts in 1839-41, some engravings being printed from his electrotypes plates in the latter year. In his process finely pulverized tin was added to the graphite for facing the moulds. The effect of this in the sulphate of copper solution was to cause a rapid precipitation of the copper by the substitution of copper for the tin; the latter being seized by the oxygen of the solution while the copper was deposited upon the graphite. The film was afterward increased by the electric current. In Silas B. Knight's modification of this process, now in universal use, fine iron filings are dusted upon the wet graphite surface of the mould, and then a solution of sulphate of copper is poured upon it and gently stirred in with a brush. A film of copper is formed immediately over the entire surface, the acid leaving the copper

and combining with the iron, forming a sulphate of iron, which floats away as more copper solution is poured on. Machinery has been devised for increasing greatly the rapidity and accuracy with which electrotypes plates can be made. The process in detail is as follows: Pure wax is melted in a kettle surrounded by a steam-chamber, and is then poured into a shallow moulding-case which has been previously heated so as to make the wax firmly adhere to it. As soon as the wax is firmly set it is run through a shaving-machine, which reduces it to a uniform thickness, and leaves a smooth surface, into which graphite dust is thoroughly rubbed in order to prevent it from sticking to the type or engraving. The impression is made by forcing the latter (also covered with graphite) into the wax to the required depth—an operation which was long performed on a hand-press, but which may now be done with great speed and perfect accuracy by power. The mould is taken from the press, the surplus wax removed with a sharp knife, and then with a hot iron new wax is melted and dropped on the surface between the lines and where there are large blank spaces. This avoids the necessity of later deepening the corresponding places on the cast plates, so as to prevent all possibility of their soiling the paper in printing. A piece of sheet-copper or lead is imbedded in the edge of the sheet of wax to facilitate electrical connection. The mould then receives a coating of graphite, and it is of the utmost importance that it should be thoroughly covered, and that the graphite should have a very high polish. The best work is done by a machine, which also obviates the great inconvenience of scattering the dust. The machine is entirely automatic. After washing the mould iron filings are sifted on, and a quantity of a weak solution of sulphate of copper is stirred in by means of a brush, a thin coating of copper being deposited upon the surface of the mould, as explained above. This operation is repeated, to make sure that every point is covered. The mould is then for one or two hours suspended as a cathode in a bath of sulphate of copper solution, and the coating is increased by the action of the electric current until it is about $\frac{1}{16}$ of an inch thick. After being detached from the mould and washed in boiling water, it is brushed on the back with a solution of chloride of zinc, and sheets of tin-foil are laid over it and melted, the face of the cast resting on a perfectly smooth surface. Molten metal is then slowly poured on, enough to give the plate the required thickness (about $\frac{1}{16}$ inch). It is cooled by an air-blast so diffused as to cause the entire plate to solidify at once, and is then subjected to pressure until quite cool and firm; if this is not done the plate is apt to become distorted, and needs to be straightened by skilful hammering. The plate is then finished to the exact size and thickness desired. Any blank spaces which are so high as to soil the paper in press are deepened, as also in stereotype plates, by a routing-machine. Plates to be used on a Hoe perfecting-press are passed through a machine which gives them the proper cylindrical curvature at one revolution. A special routing-machine is provided for such plates.

Electrotypes are sometimes faced with nickel by first placing the mould in a nickel solution and plating on a coating of the metal, and then removing to the copper solution and finishing in the regular way. Although these plates are attractive in appearance, and will not tarnish, the nickel is so liable to strip and the coating is so very thin that it is of little practical value.

Iron can be deposited by the electric current in the same manner as copper; electrotypes of iron have been made by Klein, of St. Petersburg, and the highest success is attributed to him in their application to the printing of bank-notes. The deposit is hard as steel and exceedingly durable.

Glyphography, another useful application of the art of electrotyping, is the invention of Palmer. A piece of ordinary copper plate is stained black on one side, and very thinly covered by a substance resembling white wax. The artist makes his sketch or drawing through this thin film, which wherever scraped away by his pencil exposes the black surface of the plate. The sketch when completed shows exactly what the print from an electrotypes made from the plate will be. When the artist has finished his work the remaining wax is carefully built up in the regular way, and the plate is electrotyped in the same manner as a wax mould.

By what is known as *electro-etching* this process can also be reversed, and instead of making an electrotypes from the prepared plate (the plate can be immersed in the solution and connected with the positive pole of the dynamo,

and the plate dissolved away where the lines expose it to the action of the solution. As the wax withstands the solution, the plate where covered by it will remain unchanged. When the lines are deepened by the action of the electric current and solution to the required depth, the plate is taken from the solution, and after the wax is cleaned off is mounted for printing. The drawing or sketch will appear in white lines on a black ground.

O. B. BEACH.

Sterility [from Lat. *sterilitas*, deriv. of *sterilis*, barren, sterile]: an incapacity for procreation, whether in the male or female. A knowledge of the causes of sterility depends on an understanding of the laws of conception. (See EMBRYOLOGY, OVARIES, etc.) Sterility in the male is due either to impotency or to the absence of zoöspers (spermatozoa) in the semen, or to their lack of vitality when present. If by cause of old age, malformations of the genitals, or other influences, a man is incapable of performing the part allotted by the laws of nature, he is said to be impotent, and is therefore sterile. The male may be able, however, to perform the sexual act, and yet be incapable of procreation, because the semen may not possess zoöspers, without which fructification is impossible. This deficiency may be natural or acquired; it is normal only in extreme youth and in advanced old age. If a man is born with but one testis (monorchid), as a rule it does not secrete zoöspers; and if the testes are so imperfectly developed as to remain always in the cavity of the abdomen, as in the foetus, then also the seminal fluid is deficient in the all-important property necessary for fecundation. Whatever produces an inflammation of the testes (orchitis) may bring about such a change in the secretory apparatus of these organs as to destroy the vitalizing power of the semen. A fall or a blow on these glands may do this, but the most common cause is inflammation communicated to them by continuity of surface from the urethra, neck of the bladder, and vesiculæ seminales, sequels of urethritis (gonorrhoea). Not unfrequently this happens as a consequence of parotitis (mumps), where from cold or other cause the inflammation is suddenly transferred from the parotid (salivary) gland to the testes. The seminal fluid may be emitted in a normal manner and may contain zoöspers or spermatic particles, but these may be dead or very feeble and incapable of surviving long enough to meet the ovule deep within the genital canal. This condition may be the result of some constitutional vice, drunkenness, syphilis, or excessive venery. It is estimated that 20 per cent. of sterile marriages are due to faults in the male. A man may be sterile or incapable of procreation at one time, and by appropriate treatment under favorable circumstances he may possibly regain the lost power; but the removal of incapacity in the male is not generally so successful as the removal of the obstructive causes in the female.

In the female, if competent for the married relation, and if the ovaries are functionally active, the cause of sterility is generally some obstruction to the entrance of zoöspers into the cervical canal (neck of the uterus), or a diseased condition of the mucous secretion of that canal, or some obstruction either to the exit of ovules from the ovary (periovaritis), or to the passage of zoöspers or ovules along the Fallopian tube or oviduct. If menstruation is normal, it may be taken for granted that ovulation is normal—that the ovum is at the regular time discharged from the ovary and starts on its way to the cavity of the womb; but some previous pelvic inflammation may have obstructed the Fallopian tubes or bound down their fimbriated extremities, so as to prevent them from fulfilling their functions in conducting the ovum to the cavity of the uterus. This state of things can usually be diagnosed with accuracy, but can not usually be relieved as far as sterility is concerned. Any marked and permanent deviation of the uterus from its normal position, whether anteriorly, posteriorly, laterally, or by descent, may interfere with conception. When the body of the uterus falls far forward, on the bladder, toward the pubes, it may so displace the os tincæ (outer orifice of the cervical canal) or produce such a degree of congestion in the whole organ as to prevent the zoöperm from reaching the cavity of the uterus; and if the uterus is bent on itself in this form of displacement (anteflexion), the obstruction is practically insuperable. When the body of the uterus falls far back under the hollow of the sacrum, pressing upon and obstructing the rectum, it may easily be restored to its normal position and kept there in a great majority of cases. Lateral malpositions and descent may require the same attention. A more frequent cause of the sterile condition, however, is

found in the neck and cavity of the uterus. The cavity of the uterus may contain a tumor or polypus, which must be removed, or it may be in a state of inflammation (endometritis), which must be cured. Again, the mouth of the uterus (os tincæ) may be so small that the semen can not enter it: then it must be enlarged by forcible dilatation. Abnormal angulation of that portion of the womb just above the neck (lower uterine segment) is a frequent cause of sterility. It is often bent to an acute angle instead of being comparatively straight, but when this is not complicated with the presence of a fibroid tumor or other adventitious growth, it may be remedied, and is often easily and promptly cured, by surgical means. Another frequent cause of sterility is an abnormal condition of the secretions found in the utero-cervical canal. The mucus of the cervical canal from the third to the tenth day after the end of menstruation should be translucent, clear as the white of a new-laid egg, without any opaque or milky-looking spots. A drop of mucus taken from the cervical canal a few hours after sexual intercourse should be examined under the microscope. If living zoöspers are found in abundance twenty-four hours or more after coition conception is possible; but if the zoöspers are all dead or in a dying state, then there is some abnormal condition of the utero-cervical canal which gives rise to an abnormal secretion. The diseased condition of the utero-cervical canal (called endometritis) is often found in women whose general health is perfect, and is generally curable. See also the article HYBRIDISM.

Sterilization: See DISINFECTION.

Sterlet [= Fr. = Germ., from Russ. *sterlyadt*, sterlet]: the *Acipenser ruthenus*, a small species of sturgeon found in various Russian rivers and the Caspian and Black Seas, into which they empty, and esteemed for its flesh. It is characterized by a narrow, pointed snout, and the slightly fringed barbels; the dorsal shields, 11 to 17, are moderately developed, the lateral ones, 60 to 70, small, and the abdominal, 13 to 15, moderate; the skin is densely covered with minute denticulated ossifications of subequal size. It rarely or never attains a length of 3 feet, and a common size is 2 feet in length and 3 lb. in weight. It leaves the sea in May and June, and ascends the rivers, sometimes very high up, for the purpose of spawning. It has not only a superior reputation as a table-fish, but from its roes is made the best caviare, which constitutes a noteworthy article of trade in Russia. Its introduction into rivers of the U. S. has been strongly recommended, and it has been claimed that the Mississippi and Ohio rivers would be especially suitable for it. The Russian Government has introduced it into waters about St. Petersburg, and in 1870 a number of the fry were introduced into the waters of Sutherlandshire, Scotland, in apparently good condition. Their embryonic life is so short that it is difficult to transport the eggs with success.

Revised by F. A. LUCAS.

Sterling: city; Whiteside co., Ill.; on the Rock river, and the Burlington Route and the Chi. and N. W. railways; 52 miles E. N. E. of Rock Island, 110 miles W. of Chicago (for location, see map of Illinois, ref. 2-D). It has excellent water-power; manufactures agricultural machinery, common and barbed wire, hearses, coffins, school furniture, gas-engines, and paper; and is in an agricultural region. There are 14 churches, 3 public schools, hospital, 2 national banks with combined capital of \$175,000, a private bank, and a monthly, 2 daily, and 4 weekly periodicals. Pop. (1880) 5,087; (1890) 5,824; (1895) 6,724, estimated with suburbs, 7,800.

EDITOR OF "GAZETTE."

Sterling: city (founded in 1872); Rice co., Kan.; on the Atch., Top. and S. Fé and the Mo. Pac. railways; 252 miles W. of Kansas City, Mo. (for location, see map of Kansas, ref. 6-F). It is in an agricultural and stock-raising region; is principally engaged in farming, salt-mining, and milling; and contains 18 churches, 3 public-school buildings, Cooper Memorial College, a national bank (capital \$50,000), a State bank (capital \$50,000), a private bank, and 3 weekly papers. Pop. (1880) 1,014; (1890) 1,641; (1895) estimated, 2,000.

EDITOR OF "BULLETIN AND GAZETTE."

Sterling, JOHN: author; b. at Kames Castle, Isle of Bute, July 20, 1806, son of Edward Sterling, editor of the London Times; was educated at Glasgow and Cambridge; went to London in 1827; was a short time on the editorial staff of *The Athenæum*, and during a part of 1831-32 resided for his health in the West Indies. Returning to England, he took

Donner's orders in 1834; was for a short time a curate at Harrogate, then, under Julius C. Hare, but soon gave himself wholly to literary studies and pursuits. Among his works are *Arthur Cloughly*, a novel (1833); *The Days They* (originally in *Blackwood's Magazine*, republished 1830); *Myra Thorne* (1839); *The Eltonian*, a poem (1841); and *Mistford*, a drama (1845). Two volumes of his *Essays and Tales* were edited, with a *Memoir*, by Julius C. Hare (1849), and Thomas Carlyle has written *The Life of John Sterling* (1851). D. at Ventnor, Isle of Wight, Sept. 18, 1848. Revised by H. A. BRUCE.

STERN, DANIEL: See ADOLPH.

Sterne, LAURENCE: humorist; b. at Clonmel, Ireland, Nov. 24, 1713; son of a lieutenant in the British army; educated at Jesus College, Cambridge; graduated in 1740; entered into holy orders, and was presented by his uncle with the valuable benefice of Sutton, Yorkshire, to which that of Seillington, 1½ miles distant, was soon after added. Here he lived for nearly twenty years. In 1750 he published the first two volumes of *Tristram Shandy*, which became popular at once, and gained for him from Lord Esconbridge the additional curacy of Cotswold. He had been married nearly twenty years, and now, leaving his wife and daughter at York, he went to London, where, or upon the Continent most of the remainder of his life was spent. He published several occasional sermons, and at intervals seven volumes entitled *The Sermons of Mr. Yorick, or Sermons by Laurence Sterne, A. M., Prelate of York, etc.* (1760-69). His *Life and Opinions of Tristram Shandy, Gent.*, in all nine volumes, was published at intervals (1759-67). The *Sentimental Journey*, his best work, was written in France, and published in London, 1767. D. in London, Mar. 18, 1768. In 1775 appeared three volumes of his letters to his friends, edited by his daughter, and his *Letters to Eliza, Susan, Letters by Sterne and his Friends*, edited by W. Durrant Cooper, was privately printed in 1844. Sterne was a subtle delineator of character, and a delicate artist of the pathetic and comic. His chosen province was the whimsical, and his great model in this kind was Rabelais. He was the cleverest of English sentimentalists. He was a minute philosopher, his philosophy is kindly, and he had the art of making much out of little; but his writings are morally corrupt, and his sentiment has a taint of insincerity. He was the most unclerical of clergymen, though his sermons were both witty and affecting. In character he was selfish, worldly, and vain. See the *Life of Sterne*, by Percy Fitzgerald (1864), and Thackeray's *English Humors*.

Revised by H. A. BRUCE.

Sterne, SIMON: lawyer and economic writer; b. in Philadelphia, Pa., July 23, 1830; graduated at the law school, University of Pennsylvania, 1850; removed to New York 1850; appointed in 1875 member of the commission to devise a plan for the government of cities in the State of New York, a report of which was presented to the Legislature, Feb. 24, 1887. He is the author of *Representative Government and Personal Representation* (Philadelphia, 1871); *Constitutional History and Political Development of the United States* (New York, 2d ed. 1885); and contributions to *Lalor's Cyclopedia of Political Science*. C. H. T.

Sternhold, THOMAS: hymnologist; b. near Blakeney, Gloucestershire, England, about 1500; was educated at Oxford, but did not take a degree, and became groom of the robes to Henry VIII. and Edward VI.; with John Hopkins (d. 1579) he is certainly known of him) was joint author of the first version of the Psalms into English meter. D. Aug. 1546. His first edition appeared in London in 1548, and contained nineteen Psalms; the second, *All such Psalms of David as Thomas Sternhold, late groom of the King's Majesty's robes did in his life time draw into English meter* (1549), contained thirty-seven Psalms translated by Sternhold. A 3d ed., 1551, contains seven Psalms translated by John Hopkins. Other editions followed until 1602, when *The Whole Booke of Psalmes collected into English Metre by T. Sternhold, J. Hopkins, and others, conferred with the Rheims, with apt Notes to Sing them withal*, was annexed to the Book of Common Prayer. Of the entire number of Psalms, 40 were versified by Sternhold and 50 by Hopkins. Of the *Old Version*, Julian's *Dictionary of Hymnology*. Revised by S. M. JACKSON.

STERNUM, or Breast-bone [*sternum* is Lat. Lat., from Gr. *stēron*, breast, chest]: a bony or semi-cartilaginous plate which serves as the anterior (or inferior) point of

union of many of the ribs. It represents the blended humeral spines of the dorsal vertebrae. In fishes, batrachians, and serpents it is absent. In turtles it forms the lower shell or plastron, and is much widened. In most birds it is strongly keeled in front, the keel serving as a point of attachment for the strong wing-muscles. In man it consists of three pieces, of which the uppermost is the manubrium; the next, the gladiolus; and the lowest, the xiphoid or xiphoid cartilage. The sternum may be rendered very prominent in certain bone-diseases, as rickets, by the sinking in of the ribs, which thus push the sternum forward. The chicken-breast thorax results from such deformity. Contrariwise, the sternum is sometimes sunk below the rest of the front of the chest, especially in ill-formed phthisical persons.

Sterreutiation: See SERRATION.

Sterrett, Jous Rowzer Serrington, Ph. D.: professor of Greek; b. at Rockbridge Station, Va., Mar. 4, 1801; educated at University of Virginia, University of Leipzig, Polytechnic of Aix-la-Chapelle, and Universities of Berlin, Athens, and Munich (Ph. D.); secretary American School of Classical Studies at Athens; leader of various archaeological expeditions to Asia Minor; member of the Wolfe expedition in Assyria and Babylonia; Professor of Greek in Miami University, Oxford, O., 1850-58, in the University of Texas, Austin, Tex., 1858-62, and at Amherst College, Amherst, Mass., since 1862; author of *Quæ in re Hymni Homærici quinque majores inter se differunt* (Boston, 1861); *Inscriptions of Sebaste (Asia Minor, Philol., 1863); Inscriptions of Asia, Inscriptions of Tralles, Preliminary Report of a journey to Asia Minor* (all three Boston, 1865); *An Epigraphical journey in Asia Minor, The Wolfe Expedition to Asia Minor* (both Boston, 1868); and numerous articles in *The Nation*, *The Independent*, *Classical Review*, etc. C. H. TAYLOR.

Stesichorus [= Lat. = Gr. *Στεσιχόρος*; *stēsichōros* (ancient, *stēsichōros*, *stēsichōros*, establish + *choros*, chorus): Greek lyric poet of Himera, in Sicily; b. about 650; d. about 555 B. C.; of great reputation in antiquity, especially as an inventor of poetical forms. His true name was Telesias, but he was called Stesichorus, "arranger of choruses," from his choral odes, consisting of strophes, antistrophes, and epodes, though this triple form is doubtless older. His themes were epic, and the Fourth Pythian of Pindar is supposed to give some notion of the way in which, according to Quintilian, "he sustained the weight of the epic with the lyric." On account of the poem in which he charged Helen with the woes of Troy he was fabled to have been smitten with blindness, which was removed when he withdrew his slanders in a *prothodia* or recantation. Stesichorus was also a fabulist, and to him is attributed the famous fable of the horse, the stag, and the man (Arist., *Rhet.*, II, c. 20). Of this Homer of the lyric poets we have only scant fragments, to be found in Bergk's *Poeta Lyrici Græci* (vol. III, 4th ed., pp. 205-204). B. L. GILCHRIST.

Stethoscope (from Gr. *stēthos*, chest + *skopein*, view, examine): an instrument employed by physicians for the physical exploration of the chest. (See AUSCULTATION.) Laennec, the founder of methodical auscultation, introduced the solid stethoscope, a tube made from a single piece of wood (Fig. 1). It is from 10 to 12 inches long, has a flanging chest-piece to receive sound, an open canal to convey sound, the solid structure also serving to conduct it, and a broad flat ear-piece for apposition to the ear and the exclusion of extraneous sounds. The medical profession is indebted to Dr. Camman, of New York, for originating the "binaural" or "double stethoscope" (Fig. 2). For purposes of careful diagnosis, by concentrating local sound, conducting it to the exclusion of surrounding noise, and conveying a separate but similar and simultaneous impression to each ear, the stethoscope is invaluable. It is further valuable in hospital and other public service, preventing contact of the listener's head with unhealthy and uncleanly patients. It is particularly serviceable in

FIG. 1

FIG. 2

localizing the origin of sounds, as of small cavities in the lungs, valvular diseases of the heart, and in aneurism. The best auscultators prefer the unaided ear for habitual chest examination, reserving the stethoscope to aid in special and obscure cases. The habitual use of the stethoscope blunts the delicacy of the hearing. Revised by W. PEPPER.

Stettin, *stet-teen'*: town and railway center of Pomerania, Prussia; on the left bank of the Oder, at its entrance into the Stettiner-Haff, 83 miles N. E. of Berlin (see map of German Empire, ref. 2-G). Across the river, which is here from 12 to 16 feet deep, lies the suburb of Lastadie, connected with Stettin proper by three bridges. Outside and on the line of the old fortifications, removed in 1874, are the suburbs of Bredow, Grabow, and Zülchow. The site it occupies is hilly, and its streets are consequently uneven, but the houses are neat and substantial, and many buildings, such as the royal palace, the citadel and barracks, and the town-hall, are very handsome. Its sugar-refineries, oil-mills, glass-works, breweries, distilleries, and manufactures of anchors, sailcloth, rope, tobacco, soap, candles, hats, etc., are very important, and as a place of commerce Stettin is one of the leading ports of Germany. Only small vessels can reach it, however; its port on the Baltic is Swinemünde. It is the ancient *Sedinum*, afterward *Stettinum*, and is of Slavic origin. In the Middle Ages it was the residence of the Duke of Pomerania, and, having joined the Hansa, it soon became a flourishing commercial town. It forms the outlet for the rich products of Silesian industry. Pop. (1890) 116,228.

Revised by M. W. HARRINGTON.

Steuart, Sir JAMES DENHAM: political economist; b. in Edinburgh in 1712; was educated at the University of Edinburgh, and became an advocate. While traveling on the Continent he entered into relations with the Pretender, and when the rebellion of 1745 broke out he was forced to go into exile. He returned to Scotland in 1763, and was subsequently pardoned for any share he might have had in the rebellion. He published, among other works, *Apologetic du Sentiment de Monsieur le Chevalier Newton sur l'ancienne Chronologie des Grecs* (1757) and *An Inquiry into the Principles of Political Economy* (1770), which preceded by several years Adam Smith's *Inquiry into the Nature and Causes of the Wealth of Nations*. Smith's work completely superseded Steuart's *Inquiry*, but the latter contains many valuable suggestions, and in some respects anticipates the ideas of later economists. Though he must be classed with the mercantilists, Steuart was free from many of the errors of that school of economists. D. in 1780.

Steuben, *Germ. pron. stöi'ben*, FRIEDRICH WILHELM AUGUST HEINRICH FERDINAND, Baron von: soldier; b. Nov. 15, 1730, in the fortress of Magdeburg, Prussia, where his father was an officer; entered the Prussian army as a cadet 1747; distinguished himself at the battle of Rossbach 1757; became adjutant-general 1758; was aide to Gen. Knoblauch in his brilliant march into Poland 1761; was taken prisoner and carried to St. Petersburg; won the favor of the Grand Duke Peter; was soon exchanged; was made captain (1762), and placed on the staff of Frederick the Great, from whom he received, with a few other selected officers, special instruction in tactics; was appointed in 1764 grand marshal to the court of the Prince of Hohenzollern-Hechingen, but resigned that post about 1775. In 1777 he was induced by Saint-Germain to offer his services to the American insurgents through the agency of Silas Deane, and was appointed, inspector-general, with the rank of major-general, in the spring of 1778; took part as a volunteer in the battle of Monmouth in the following June; rendered memorable services in drilling the officers and men of the Continental army into efficiency; prepared a manual of instruction for the army, adopted by Congress and printed 1779; was a member of the court martial on Maj. André; took command of the forces in Virginia 1780, and rendered good services at the siege of Yorktown 1781. His greatest exploit, however, was his Virginian campaign. He had been left in Virginia by Gen. Greene to gather up and discipline the levies voted for the Southern army by that State when it was invaded by Arnold. On the appearance of this new danger the militia flocked to Steuben's standard. Arnold succeeded in burning Richmond, and then went down the James river on a marauding expedition; but when pursued and overtaken by Steuben with the militia, he fled up the Elizabeth river. Remaining as a citizen of the U. S. after the war, Steuben procured with difficulty an adjustment of his claims upon Congress. He was ultimately assigned a pension of \$2,500

and received grants of land from several States. On the tract given him by New York, in Oneida County (the township of Steuben), he settled, accompanied by North, Poplar, Walker, and others of his former aides, to whom he gave a large portion of his lands. D. at Steuben, Nov. 28, 1794. He was a man of great kindness and generosity, of ready wit and highly polished manners. A *Life* by Francis Bowen appeared in Sparks's series; another, containing much new material, was published by Friedrich Kapp (1860), and an epitome of the latter may be found in Greene's *German Element in the War of Independence* (1876).

Steubenville: city (site of a fort built in 1786, laid out as a town in 1798, incorporated as a city in 1851); capital of Jefferson co., O.; on the Ohio river, and the Cleveland and Pittsburgh Div. of the Penn., the Pitts., Cin., Chi. and St. L., and the Wheeling and Lake Erie railways; 22 miles N. of Wheeling, and 43 miles W. of Pittsburg (for location, see map of Ohio, ref. 4-J). It is in a rich agricultural and mining region; is laid out on the second terrace of the Ohio, above danger from the floods for which the river is noted, and is nearly surrounded by hills from 300 to 500 feet high, which protect it from destructive winds. The city has excellent surface drainage, good sewerage, and a water-supply obtained from the river 2 miles above the city, with a system of high-pressure mains for fire and manufacturing purposes and one of low-pressure for domestic uses. The principal streets are paved with vitrified brick.

Churches and Schools.—Steubenville has 5 Methodist Episcopal churches, 3 Presbyterian, 2 Roman Catholic, 2 Lutheran, and 1 each African Methodist Episcopal, Baptist, Congregational, Christian, Methodist Protestant, Protestant Episcopal, and United Presbyterian. The public-school system comprises 6 school buildings, 54 teachers, and over 2,200 pupils, and in 1893-94 cost for maintenance over \$37,000. There are 2 Roman Catholic parochial schools, with over 500 pupils. The Steubenville Female Seminary, founded in 1829, has been enlarged in scope by the addition of a college preparatory department for both sexes. There are several libraries and 3 daily and 8 weekly newspapers.

Finances and Banking.—In 1893 the receipts for municipal purposes were \$113,243; expenditures, \$87,479; net debt was \$24,655; assessed property valuation, \$5,624,100. In 1894 there were 2 national banks with combined capital of \$225,000, 3 private banks, and a building and loan association.

Business Interests.—In the surrounding hills and underlying the city are extensive supplies of excellent coal. The seam beneath the city limits is worked by means of several shafts. Natural gas is abundant at distances of from 5 to 50 miles, and is piped into the city; petroleum-wells have been opened within 5 miles; and economic clays are easily mined in the hills. The principal manufactures are 3 blast-furnaces, 2 rolling-mills and nail-factories, 2 foundries, 2 machine-shops, steel plant, boiler-works, 5 glass-factories, 2 flour-mills, glass-melting pot-works, paper-mill, white-ware pottery, and ice plant. Extensive fire-brick, paving-brick, and sewer-pipe works, N. of the city, form a part of the local industries, as do also numerous coal mines and quarries of building-stone in the vicinity, operated by local capital. The greater part of the coal product is shipped to the lakes. The city is the distributing point for a large area of country. Pop. (1880) 12,093; (1890) 13,394.

H. N. MERTZ, SUPERINTENDENT OF PUBLIC INSTRUCTIONS.

Stevens, ABEL, LL. D.: minister and author; b. in Philadelphia, Pa., Jan. 19, 1815; studied at the Wesleyan University, Middletown, Conn.; joined the New England Conference of the Methodist Episcopal Church in 1834, was agent for the Wesleyan University one year, and in 1835 was stationed at Boston; in 1837 made a European tour, and after his return was stationed at Providence, R. I.; in 1840 became editor of *Zion's Herald* at Boston, and in 1852 of *The National Magazine*, an illustrated monthly, at New York, which was discontinued after two or three years. In 1856 he was elected by the general conference as editor of the New York *Christian Advocate and Journal*. From 1860 to 1874 he was joint editor of *The Methodist*, an independent journal published in New York. He has published numerous books, including *Memorials of the Introduction of Methodism into New England* (1848); *Memorials of the Progress of Methodism in the Eastern States* (1852); *Church Polity*; *History of the Religious Movement called Methodism* (3 vols., 1858-61); *Life and Times of Nathan Bangs, D. D.* (1863); *History of the Methodist Episcopal Church*

in the *United States of America* (4 vols., 1864-67; vol. v. in press, 1895); *The Centenary of American Methodism* (1866); *The Women of Methodism* (1866); *Life and Times of Madame de Staël* (2 vols., 1882); *Character Sketches* (1882); and *Christian Work and Consolation* (1885).

Revised by A. OSBORN.

Stevens, ALFRED: genre-painter; b. in Brussels, May 11, 1828; studied at the École des Beaux-Arts and under Roqueplan, Paris; third-class medal, Salon, 1853; second-class, Paris Exposition, 1855; first-class, Paris Exposition, 1867 and 1878; medal of honor, Paris Exposition, 1889; commander Legion of Honor 1878; commander in the Orders of Leopold of Belgium, Francis Joseph of Austria, and St. Michael of Bavaria. He is one of the ablest and most charming painters of modern life in the French school, to which, by residence and affinities, he belongs, and his works are especially fine in color quality. An excellent example of his style is *Five o'clock Tea*, in the collection of Mrs. W. H. Vanderbilt, New York. Studio in Paris.—His brother JOSEPH, born in Brussels, 1822, is distinguished as a painter of dogs and other animals. Among his works are *Tauureau flamand poursuivi par un Chien* (1853) and *Chien regardant une Mouche* (1878).

WILLIAM A. COFFIN.

Stevens, ALFRED GEORGE: sculptor; b. at Blandford, Dorsetshire, England, in 1817. He was the son of a house-painter and decorator, and was sent to Italy at the expense of a wealthy gentleman to study painting. He returned to England about 1842, and was made a teacher in the Government School of Design, then established at Somerset House, London, in which he remained about four years. During this time he made many designs for ornamental work of various kinds, such as the doorway of the Jermyn Street School of Mines, the doors themselves having been designed also by him but never carried further than the fine drawing in South Kensington Museum. As designer for the Green Lane works at Sheffield he made, about 1851, some remarkable fire-places and stoves, anticipating by many years the work of 1885-95 in modern adaptation of classical ornament. Of the years from 1850 to 1860 are some remarkable designs for pottery, daggers, and other small objects, and then, or at a later time, he designed the decorations of many very costly houses. He made designs, in competition, for the painted decorations of some of the halls of the new Houses of Parliament, for the decorations of the new Foreign Office, and for a memorial of the Exhibition of 1851. In 1857 he competed for a monument to the Duke of Wellington, and, among eighty-two competitors, was so far successful as to receive one of the minor prizes, and at a later time to be employed as designer of the work. His design was partly carried out, and the monument in a small chapel of St. Paul's Cathedral is what exists of it. The architectural design of the monument is fine and worthy of the occasion, but not very original. The sculpture is of very great merit. This was to consist of the equestrian statue on the summit, which, however, was never finished, and the following, which is all in place: A recumbent figure on a sarcophagus, a group of *Valor and Cowardice*, and one of *Truth and Falsehood*, besides decorative panels. D. in London, Apr. 30, 1875.

RUSSELL STURGIS.

Stevens, CHARLES ELLIS, Ph. D., LL. D., D. C. L.: clergyman; b. in Boston, Mass., July 5, 1853; studied at Wooster University, Ohio, University of Pennsylvania, Yale College, Berkeley Divinity School, Middletown, Conn., Nashotah, Wis., and in Europe; ordained priest in the Protestant Episcopal Church 1875; assistant minister of Grace church, Brooklyn, N. Y., 1876; rector Church of the Ascension, Brooklyn, 1877; for many years from 1878 secretary of an auxiliary of the board of missions of the Protestant Episcopal Church and chairman of numerous committees of the diocese of Long Island; examining chaplain diocese of Long Island; archdeacon of Brooklyn 1888-91; president of League for Moral Instruction in Public Schools of New York 1890; rector Christ church, Philadelphia, 1891; lecturer on English and American constitutional law, Wooster University, 1888, at the University of the City of New York 1891, and at the University of Pennsylvania 1892; lecturer on constitutional law and English literature at St. Stephen's College, Annandale, N. Y., since 1890; received honorary degrees from Wooster University and King's College, Nova Scotia; fellow of Society of Antiquaries, Edinburgh, the Royal Geographical Society, and other learned societies; has in preparation a work entitled *Sources of the Constitution of the United States*.

Stevens, EBENEZER: soldier; b. in Boston, Mass., Aug. 22, 1751; was a member of Paddock's Company of Boston Artillery, and one of the famous "Boston tea-party" Dec., 1773; removed soon afterward to Rhode Island; raised two companies of artillery and one of artificers for the expedition against Quebec, in which he served as lieutenant, having been commissioned May 8, 1775; became captain of Knox's regiment Jan. 11, and brevet-major Nov. 9, 1776; commanded the artillery at Ticonderoga and at Stillwater; was appointed lieutenant-colonel Apr. 30, 1778; was assigned to Lamb's regiment; served under Lafayette in Virginia; was, alternately with Lamb and Carrington, in command of the artillery during the siege of Yorktown; was one of the founders of the Society of the Cincinnati, and became after the war a leading merchant of New York in the West India and Mediterranean trade; agent of the War Department, and a major-general of militia. D. at Rockaway, L. I., Sept. 2, 1823.

Stevens, EDWIN AUGUSTUS: inventor; b. at Hoboken, N. J., in 1795; son of John and brother of Robert L. Stevens; took part in their steamboat experiments and enterprises, and in conjunction with his brothers established passenger and tow boats on the Hudson and other rivers; also aided in the introduction of railways, and invented many appliances for use thereon. At the breaking out of the civil war he urged the Government to put in service the ironclad floating battery of which his brother had long before undertaken the construction, offering to complete it at his own risk, and to receive payment only in case it should prove successful; this offer being declined, he expended considerable sums on the vessel, and upon his death bequeathed it to the State of New Jersey, together with \$1,000,000 for its completion; this, however, proved insufficient, and the battery was never finished, and was finally sold to dealers in old iron. He inherited a large fortune from his father and brothers, endowed the Hoboken High School, and bequeathed nearly \$1,000,000 to establish at Hoboken the Stevens Institute of Technology. D. in Paris, Aug. 7, 1868.

Revised by R. H. THURSTON.

Stevens, GEORGE BARKER, D. D.: clergyman and educator; b. at Spencer, N. Y., July 13, 1854; graduated at the University of Rochester, New York, 1877, and at the Yale Divinity School 1880; pastor of the First Congregational church, Buffalo, N. Y., 1880-83, of the First Presbyterian church, Watertown, N. Y., from 1883 to 1886, when he was appointed Professor of Criticism and Interpretation in Yale Divinity School. Besides reviews, essays, etc., he has edited Chrysostom's *Homilies on the Acts and the Romans* (1889), and published a *Commentary on the Epistle to the Galatians* (1890), *The Pauline Theology* (1892), and *The Johannine Theology* (1894).

GEORGE P. FISHER.

Stevens, HENRY: bibliographer; son of Henry Stevens, antiquary; b. at Barnet, Vt., Aug. 24, 1819; studied at Middlebury College 1838-39; graduated at Yale College 1843, and at Cambridge Law School 1844; established himself in London 1845 (where he resided till his death) as agent for the British Museum in the purchase of North and South American books of all kinds, and was thus instrumental in placing in the British Museum a very complete collection of Americana. He also purchased for the Smithsonian Institution, the Library of Congress, and the chief libraries of the U. S., and for many private individuals. He published several valuable bibliographical treatises and catalogues, among which are *A Catalogue Raisonné of English Bibles* (1854); *A Catalogue of the American Books in the Library of the British Museum* (1856); *A Catalogue of the Crowninshield Library* (1860), and of the library of Baron Humboldt (1861), which latter collection he had purchased; *Bibliotheca Americana* (1861); *Historical Nuggets* (1862); *Bibliotheca geographica et historica* (1870), the latter book being the catalogue of the library of his father, of whom it contains a biographical sketch; *The Bibles in the Canton Exhibition* (1878); *Historical Collections* (2 vols., 1881-86); and *Recollections of James Lenox* (1886). He also prepared indexes to the State papers in London relating to New Jersey (1858), Maryland (10 vols.), Rhode Island (6 vols.), and Virginia (1858), the three latter being in MS.; published a work on *The Tehuantepec Railway* (1869), and two small volumes of *Historical and Geographical Notes* (1869), relating to early explorations in America. He frequently wrote after his name the initials G. M. B. (= Green Mountain Boy). D. in London, Feb. 28, 1886.

Revised by S. M. JACKSON.

Stevens, ISAAC INGALLS: soldier; b. at Andover, Mass., Mar. 28, 1818; graduated at the U. S. Military Academy July 1, 1839; promoted second lieutenant of engineers; was engaged upon construction and repairs of fortifications 1839-46; served in the war with Mexico as adjutant of engineers, participating in all the battles from Vera Cruz to the city of Mexico, and for gallantry at Contreras and Churubusco and at Chapultepec was breveted captain and major, and was severely wounded in the San Cosme suburb. From 1849 to 1853 he was principal assistant and in charge of the office of the U. S. Coast Survey at Washington; in Mar., 1853, resigned from the army to accept the governorship of Washington Territory; conducted the pioneer survey of the route for the Northern Pacific Railroad, an account of which he published; delegate to Congress from Washington Territory 1857-61; on the outbreak of the civil war was made colonel of the Seventy-ninth (Highlanders) New York Volunteers. Moving his command to Washington, he was made a brigadier-general of volunteers Sept. 28, and attached to the Port Royal expedition, which left Hampton roads a month later. He commanded the land forces in the actions at Port Royal Ferry, Coosaw river, and a division in the actions on Stono river and the assault on Secessionville. On July 4, 1862, he was made a major-general of volunteers, and a week later transferred to Newport News in command of a division; at the second battle of Bull Run his division (Ninth Corps) was hotly engaged. Near Chantilly, on the morning of Sept. 1, 1862, his division encountered the enemy, when Stevens, ordering a charge, placed himself at the head of his command, where he was shot through the head and instantly killed.

Revised by JAMES MERCUR.

Stevens, JOHN: inventor; b. in New York in 1749; graduated at King's (Columbia) College in 1768, and was admitted to the bar, but did not practice; became interested in the question of navigation by means of steam, and as early as 1789 presented a memorial to the New York Legislature stating that he had perfected his plans, and in 1804 launched a small vessel worked by steam with screws, and in 1807 built a steamboat which he called the *Phoenix*. Fulton had in the meantime built his steamboat, the *Clermont*, and obtained the exclusive right of navigating the Hudson by steam, and Stevens sent his vessel to the Delaware river. In 1812 he planned a revolving steam-battery, to be plated with iron, and involving essentially the principles afterward embodied in the monitors, and in the same year put forth an essay on railways, indicating the methods of operating them by steam, and suggested the construction of a railway from Albany to Lake Erie. The Camden and Amboy Railroad was planned by him. He once owned the entire site of Hoboken, N. J., and through profits in real estate and other enterprises amassed an immense fortune. D. at Hoboken, Mar. 8, 1838.

Revised by R. H. THURSTON.

Stevens, JOHN LEAVITT, LL. D.: writer and diplomat; b. at Mt. Vernon, Me., in 1820. He was educated in the schools and seminaries of his native State. In 1855 he became partner and coeditor with James G. Blaine of *The Kennebec Journal*, of which he subsequently was chief editor for many years; member of the Legislature 1865-70; U. S. minister to Uruguay and Paraguay 1870-73. In 1877 he was appointed minister to Sweden and Norway. During his official residence of six years in Stockholm he wrote the *History of Gustavus Adolphus*. In 1883 Tufts College conferred on him the degree of LL. D. In 1889 he was appointed minister resident to the Hawaiian islands, a title soon after changed, by act of Congress, to that of minister plenipotentiary and envoy extraordinary. He was recalled in 1893, his attitude during the revolution in the islands being condemned by President Cleveland as compromising the neutrality of the U. S. D. at Augusta, Me., Feb. 8, 1895.

Stevens, ROBERT LIVINGSTON: inventor; b. at Hoboken, N. J., Oct. 18, 1787; son of John Stevens, inventor; became early interested in the ideas of his father regarding steam navigation, and made many improvements in the construction of vessels, among which was that of giving concave water-lines to the hull. He subsequently engaged largely in the building of steamboats, improving the marine engine, and introducing the beam engine. In 1813 he invented and made for the Government elongated percussion shells for smooth-bore guns, and in 1822 used anthracite coal in a furnace, and soon after in his steamers; in 1836 introduced the T-rail on the Camden and Amboy Railroad, of which he was president, and in 1842 was commissioned to build for

the U. S. Government an iron-plated floating battery, which remained uncompleted at his death. D. at Hoboken, Apr. 20, 1856.

Revised by R. H. THURSTON.

Stevens, THADDEUS: statesman; b. at Peacham, Vt., Apr. 4, 1792; graduated at Dartmouth College in 1814; went to Gettysburg, Pa., where he taught in an academy, at the same time studying law; was admitted to the bar in 1816, and soon acquired an extensive practice. In the presidential canvass of 1828 he was a strong opponent of the election of Gen. Jackson; in 1833 and several times subsequently he was a member of the State Legislature, in 1836 a member of the convention to revise the State constitution, and in 1838 canal commissioner. He was active in introducing the public-school system in Pennsylvania. In 1843 he removed to Lancaster; in 1848 was elected Representative in Congress; was re-elected in 1850, 1858, 1862, and thereafter to each Congress until his death, serving at various times as chairman of important committees, being one of the acknowledged leaders of the Republican party, and distinguishing himself for his earnest advocacy of measures in opposition to slavery, for the emancipation and enfranchisement of the colored race, and after the war for stringent proceedings against the seceding States. He was one of the most active managers in the impeachment trial of President Johnson. The degree of LL. D. was conferred upon him by Middlebury College in 1867. D. at Washington, Aug. 11, 1868.

Stevens, WALTER LE CONTE, Ph. D.: physicist; b. in Gordon co., Ga., June 17, 1847; graduated at the University of South Carolina 1868; instructor in chemistry, Oglethorpe College, Atlanta, Ga., 1870-72; teacher of physical science, Chatham Academy, Savannah, Ga., 1873-76. After a year at the University of Virginia he taught in New York until 1882, at the same time writing on physiological optics and acoustics in *The American Journal of Science*, *London Philosophical Magazine*, and other journals. He was Professor of Mathematics and Physics in the Packer Collegiate Institute, Brooklyn, N. Y., 1882-90; studied physics at Strassburg, Berlin, and Zurich from 1890 to 1892, when he became Professor of Physics in the Rensselaer Polytechnic Institute, Troy, N. Y. Besides contributions to various periodicals he wrote a large part of *Appletons' Physical Geography* (New York, 1887) and revised *Steele's Physics* (1888).

Stevens Institute of Technology: a school of mechanical engineering at Hoboken, N. J., founded in 1870 by a bequest from Edwin A. Stevens, and further assisted by donations by its president, Henry Morton. It prepares young men for employment in manufacturing establishments, on railways, and the like, where machinery is designed, constructed, and operated. Its course of studies comprises departments of mathematics, mechanical drawing, physics, general chemistry, analytical chemistry, mechanical engineering, experimental mechanics and shop-work, applied electricity, languages, belles-lettres, and engineering practice. Its course has been especially characterized by its large admixture of practical work in the line of workshop practice, in the handling of machine tools, and particularly in dealing with experimental problems, such as the operation of steam, gas, and hot-air engines, pumps, injectors, etc., with accompanying measurements of their efficiency by the use of indicators, dynamometers, calorimeters, etc. A department of applied electricity was established in 1883 and a chair of engineering practice was founded in 1888. The buildings include, besides lecture-rooms and drafting-rooms, chemical and physical laboratories, machine-shops, foundries, and other provisions for practical mechanical and electrical work. The faculty numbers eighteen, many of whom are leaders in their departments as original investigators and authors. The students number upward of 250, and on graduation receive the degree of mechanical engineer.

HENRY MORTON.

Stevenson, ALAN: engineer; son of Robert Stevenson (1772-1850); b. in Edinburgh, Scotland, 1807; educated at the University of Edinburgh; subsequently studied natural philosophy under Sir John Leslie, and for the profession of a civil engineer in the office of his father, with whom he entered into partnership. In 1843 he succeeded his father as engineer to the commissioners of northern lighthouses, to which his subsequent practice was confined. Among many other important improvements in lighthouse apparatus, he introduced the dioptric system in 1836. Of the many lighthouses designed and constructed by him, the Skerryvore was his chief work, an *Account of which* he published; also a *Treatise on Lighthouse Illumination*; contributed

articles *Harbors, Lighthouses, etc.*, in the *Encyclopædia Britannica*, and various scientific articles in the *Edinburgh Philosophical Journal*, etc. The Emperor of Russia and the Kings of Prussia and Holland bestowed medals upon him in recognition of his services as a lighthouse engineer. He was a fellow of the Royal Society of Edinburgh, member of the British Institution of Civil Engineers, etc. D. at Portofino, near Edinburgh, Dec. 29, 1895.

Stevenson, Robert Louis BALFOUR; author; b. in Edinburgh, Scotland, Nov. 13, 1850. He was grandson of Robert Stevenson, a distinguished engineer, and son of Thomas Stevenson, author of *Lighthouse Optics*. (See *Thomas Stevenson in Memoirs and Portraits*.) His ancestors for three generations had been civil engineers in the service of the board of northern lighthouses, and Robert, who was educated at the University of Edinburgh, was at first intended for the same profession. He was also admitted to the Scottish bar, but did not engage in practice. He first attracted attention as an author by two charmingly sketchy and vagabondish little volumes, *An Inland Voyage* (1878) and *Travels with a Donkey* (1879). These were followed by a series of romances, *New Arabian Nights* (1882); *Treasure Island* (1883), a tale of buccannery and buried treasure and one of the best boy's books; *Prince Otto* (1885), a love story; *The Strange Case of Dr. Jekyll and Mr. Hyde* (1885), a psychological romance, and the most popular of Stevenson's fictions; *Kidnapped* (1886), a novel with historical elements and studies of Scottish character-types quite equal to Sir Walter Scott's; *The Merry Men and other Tales* (1887), a volume of short stories in a variety of keys; *The Master of Ballantrae* (1888); *The Wrecker* (1893, with Lloyd Osbourne); *David Balfour* (1893), a sequel to *Kidnapped*, etc. Stevenson's versatility is shown in his *A Child's Garden of Verses* (1895), a very imaginative, poetic representation of the world from the childish point of view, and in various volumes of travel, criticism, miscellaneous essays, and sketches, such as *Virginibus Puerisque* (1881); *Across the Plains* (1882); *The Silverado Squatters* (1883); and *Memoirs and Portraits*. He traveled much in search of health, and many of his books were written in a sick-bed, on railway journeys, or at sea. For a number of years he resided at Samoa and elsewhere in the South Sea Islands, reporting his observations in *A Footnote of History* (1892), *Island Nights Entertainments* (1900), and other volumes. In an age of realism Stevenson brilliantly advocated the claims of romance both by practice and by theory. D. at Vallima, Samoa Islands, Dec. 3, 1894. H. A. BEERS.

Stevens Point; city; capital of Portage co., Wis.; on the Wisconsin river, and the Gr. Bay, Winona and St. P. and the Wis. Cent. railways; 21 miles N. E. of Grand Rapids, 71 miles N. of Portage (for location, see map of Wisconsin, ref. 5-D). It is at the base of one of the most valuable pine districts of the West; has large lumbering interests and abundant water-power; and contains water, gas, and electric-light plants, numerous saw, shingle, and planing mills, foundries, railway machine and repair shops, flour-mills, 2 national banks with combined capital of \$150,000, a State bank with capital of \$50,000, and 4 weekly newspapers. Pop. (1880) 4,449; (1890) 7,895.

Stewardship of the Children Hundreds: See *CANTON LUDLOW*.

Stewart, Alexander TURNER; merchant; b. near Belfast, Ireland, Oct. 27, 1803; distinguished himself at school, and was entered at Trinity College, Dublin, where he did not graduate. He emigrated to New York in 1829, bringing with him a few hundred pounds, a part of a small estate which he inherited, and for a time taught mathematics and the classics in a private school. Having invested his ready money in a small mercantile venture, he found himself unexpectedly left alone in the business with the rest of the stock on his hands and was forced to become a trader. Returning to Ireland, he sold his other property, invested the proceeds in Irish lace and similar goods, and in 1835 opened a small store in Broadway, and began the business which afterward grew to be the most extensive dry-goods establishment in the world, with branches in England, Scotland, Ireland, France, and Germany, besides large manufactories of woollen, carpets, and hosiery in the U. S. and Great Britain, the whole employing about 8,000 persons. At the time of his death it was said that only two men in the U. S. were more wealthy than he. Among his enterprises was the establishment of a town called Garden City, on Long Island, a few miles from Brooklyn. During the civil war he was

an earnest upholder of the national Government, and in 1860 accepted from President Grant the nomination as Secretary of the Treasury. The nomination was withdrawn, it being found that he was rendered legally ineligible for that position on account of his being engaged in the importation of foreign merchandise. He was president of the honorary commission sent by the U. S. Government to the Paris Exposition of 1867. D. in New York Apr. 10, 1876, leaving no children. By his will his entire estate, with the exception of certain legacies, was devised to his wife, To Mr. Hilton, his legal adviser, was left a legacy of \$1,000,000.

Stewart, BALDWIN F. R. S.; physicist; b. in Edinburgh, Scotland, Nov. 1, 1828; educated at the Universities of St. Andrews and Edinburgh; settled in Australia, where he was engaged in business in Melbourne 1852-54; returned to Great Britain 1855; was for three years assistant to Prof. Forbes in Edinburgh in his lectures and experiments upon mechanics; was appointed director at Kew, July 1, 1859, and Professor of Natural Philosophy at Owens College, Manchester, 1870. He was the discoverer of the law of equality between the absorptive and radiative powers of bodies, for which he received the Rumford medal of the Royal Society, 1866; was author, jointly with Messrs. De la Rue and Loewy, of *Researches in Solar Physics*, and, with Prof. P. G. Tait, of papers giving the results of experiments on *Heat produced by Rotation in Vacuum*, and of a religious-scientific treatise, *The Unseen Universe* (1873); contributed numerous papers, chiefly on meteorology and terrestrial magnetism, in the *Transactions of the Royal Society*, and published *Elementary Lessons in Physics* (1870); *Elementary Treatise on Heat* (1871); the *Physics Primer* (1872); and the *Conservation of Energy* (1873) in the International Scientific Series, D. at Drogheda, Ireland, Dec. 10, 1897.

Stewart, CHARLES; rear-admiral U. S. navy; b. in Philadelphia, Pa., July 28, 1778; went to sea at the age of thirteen as cabin-boy in a merchant vessel, and before he was twenty had become captain of an Indianan. In 1798 he entered the U. S. navy as lieutenant, and in July, 1800, was appointed to the command of the *Experiment*, a schooner of 22 guns, with which, Sept. 1, he captured the French privateer *Deux Amis*, 8 guns, and soon after the *Diana*, 14 guns, also recapturing several U. S. vessels which had been taken by the French. In 1804, in command of the brig *Siren*, he took part in the naval operations against Tripoli, aiding Decatur in the destruction of the U. S. frigate *Philadelphia*, which had fallen into the hands of the Bey of Tripoli. He was made captain in 1806; in the summer of 1813 took command of the frigate *Constitution*, 32 guns, and in December sailed from Boston for the West Indies, making several captures of British vessels. In Dec. 1814, he sailed on a second cruise, and on Feb. 20, 1815, captured the British ship *Cyane*, 34 guns, and the *Levant*, 21 guns. The action was fought at night, and lasted forty minutes; the *Levant* was, however, recaptured by a British squadron. In 1816-20 Stewart commanded the Mediterranean squadron, in 1821-23 that of the Pacific, subsequently serving on the board of navy commissioners, as commander of the home squadron, and of the naval station at Philadelphia. He was placed on the retired list in 1837, but resumed service in 1859, and was placed in command of the *Philadelphia* navy-yard with the rank of senior flag officer, and in 1862 was made rear-admiral on the retired list. D. at Bordentown, N. J., Nov. 7, 1869. Revised by C. BELKNAP.

Stewart, DAVID, Duke of Rothesay and Earl of Carrick; son of Robert III., King of Scotland; b. about 1377; became lieutenant of Scotland, subject, however, to the advice of his council, of which his uncle, the Duke of Albany, was a member. He defended Edinburgh against Henry IV. of England 1400, but was soon after seized by the opposite party and imprisoned in Falkland Castle, where he died by starvation 1401.

Stewart, DUGALD; philosopher; b. in Edinburgh, Nov. 29, 1752; son of Matthew Stewart, Professor of Mathematics in the University of Edinburgh; studied there and at Glasgow; was in 1774 appointed assistant professor to his father, whom he succeeded in 1785. In the same year receiving the chair of Moral Philosophy. In 1810 he resigned his chair on account of failing health, and passed the remainder of his life in literary labor at his seat on the Firth of Forth, the sincere office of gazette-writer for Scotland having been created for him. The following are his principal works: *Elements of the Philosophy of the Human Mind* (1792); *Outlines of Moral Philosophy* (1793); *General View of the*

Progress of Metaphysical, Ethical, and Political Philosophy, prefixed to the supplement to the *Encyclopædia Britannica* (1816); *The Philosophy of the Active and Moral Powers of Man* (1828). He also wrote biographies of Adam Smith, Thomas Reid, and Dr. Robertson. The best edition of his collected works is that prepared by Sir William Hamilton (1856). D. in Edinburgh, June 11, 1828.

Revised by J. MARK BALDWIN.

Stewart, ESME: Lord of Aubigny, Earl and Duke of Lennox; b. in France about 1555; grandson of John, third Earl of Lennox; derived his French title from Sir John Stewart of Darnley, constable to the Scots army in France in the wars of Charles VII.; arrived in Scotland in Sept., 1579, and immediately became a favorite of his cousin, King James VI., who created him Earl of Lennox Mar. 5, 1580, Duke of Lennox and Earl of Darnley Aug. 5, 1581; took an active part in the political intrigues of the time, instituting legal proceedings against the ex-regent Morton, and secured his condemnation and execution for the murder of Darnley; quarreled with the Church, and was accused of treason, and expelled from Scotland Dec., 1582. D. in Paris, May 28, 1583.

Stewart, MATTHEW: Earl of Lennox, regent of Scotland; b. in Scotland about 1510; married Lady Margaret Douglas, and had by this marriage two sons, of whom the elder, Earl Darnley, married Mary Queen of Scots. He was prominent in the movement which resulted in the seizure and imprisonment of the queen at Lochleven Castle, June 15, 1570; was the next day declared lieutenant-governor of Scotland in behalf of his grandson, the infant Prince James VI.; was elected regent July 12; conducted the war against the partisans of Mary; took Dumbarton Castle Apr., 1571, but was unable to secure that of Edinburgh; held a Parliament at Leith May 9, 1571, and when on his way to hold a Parliament at Stirling was attacked and mortally wounded by a party of the queen's friends. D. at Stirling, Sept. 4, 1571.

Stewart, ROBERT: See CASTLEREAGH, VISCOUNT.

Stewart, WILLIAM, D. D.: minister and professor; b. at Annan, Dumfriesshire, Scotland, Aug. 15, 1835; educated at the University of Glasgow; minister in the parish of St. George's-in-the-Fields, Glasgow, 1868-75; in the University of Glasgow examiner in mental philosophy for degrees 1867-70, and since 1873 Professor of Divinity and Biblical Criticism. Dr. Stewart has published *The Divinely Established Connection between the Old Testament and the New* (1873); *The Plan of St. Luke's Gospel* (1873); a revised and edited translation of vols. xi. and xiv. of Meyer's *Commentary on the New Testament* (1879-80); *The Church of the Fourth Century* (1883); and *The University of Glasgow, Old and New, Illustrated* (1891). C. K. HORT.

Stewart Island, also called **New Leinster:** the southernmost and smallest of the three chief islands of New Zealand. It is of triangular form, about 100 miles in circumference, with an area of 665 sq. miles; consists largely of hills, of which there are three ranges; the highest summit is Mt. Anglem in the northern part, 3,200 feet; is separated from New Zealand by Foveaux Strait, 20 miles wide, and forms a part of the province of Southland. It is well wooded and watered, has much mineral wealth, and some fertile valleys, and the waters surrounding it abound in fish and oysters. The population is sparse, mostly Maoris or half-castes.

Revised by M. W. HARRINGTON.

Stewartry: the name which was given in Scotland to a district governed by a steward, which officer was appointed by the king with jurisdiction over crown lands and powers similar to those of a lord of regality. While the civil jurisdiction of a steward was equivalent to that of a sheriff, his criminal jurisdiction was much more extensive. The only remaining trace of that jurisdiction exists in the term stewartry, which, in place of county, is applied to the district of Kirkcudbright. The reorganization of the office took place in 1747, but the name was continued until 1 Vict., c. 39, substituted the name sheriff for it.

Stib'ium: the Latin name of ANTIMONY (*q. v.*).

Sticking-plaster, or Adhesive Plaster: an article for surgeons' use, made of resin, lead plaster, and soap, melted together and spread by machinery upon stout muslin. It is of great value in practical surgery, but requires rather frequent renewal, as it loses its adhesive qualities. It has to be warmed before application, but is not loosened by wetting. Light adhesive plasters, court-plasters, and the like, are made of silk or goldbeater's skin, covered on the adhesive side

with a solution containing isinglass and gum-benzoin, while the back of the plaster receives a varnish of Chian turpentine and benzoin. These plasters are wetted before application.

Revised by H. A. HARE.

Stickleback [*M. Eng. stickle, prickle, spine + back*]: a hemibranchiate fish of the family *Gasterosteidae*, having the back armed with stout spines, whence the popular name. (See HEMIBRANCHII.) The form is more or less elongated; the body naked or covered with lateral plates; head compressed, more or less pointed; dorsal fin represented by a variable number of free stout spines (2-15) and an oblong fin with articulated rays; ventral fins represented by enlarged spines with an axillar ray each, and inserted more or

The stickleback (*Gasterosteus aculeatus*).

less behind the basis of the pectorals. The species with two or three free dorsal spines belong to the genus *Gasterosteus*, those with four to *Eucalia*, those with from seven to nine to *Pygosteus*, those without a bony cuirass between the ventrals to *Apeltes*, and the elongated salt-water species with fifteen spines to *Spinachia*. The species rarely exceed 6 inches, and are generally very much less. Although so small, they are nevertheless extremely pugnacious and voracious, and attack without hesitation animals many times larger than themselves. In the breeding season the males assume resplendent hues, which are very changeable. The males construct nests of particles of grass, roots, sticks, or leaves, which are united together by a viscid mucus or silk-like thread exuded from the body and wound round the material collected. The male seeks out a gravid female, conducts her to the nest, and she deposits a few eggs, and then escapes by an aperture already made or which she herself makes opposite to the one she entered by. This is repeated day after day until a considerable number of eggs is accumulated. Each time the male rubs himself against the female and passes over the eggs. For a month, while the eggs are maturing, the male watches over them with jealous care, and only leaves when the young are hatched and ready to care for themselves. The eggs are large in proportion to the size of the fish, and few in number, not much, if at all, exceeding 100 in the common two-spined sticklebacks.

Stigma: See PISTIL.

Stigmatiza'tion [from Lat. *stigmatiza'tio*, deriv. of *stigmatiza're*, from Gr. *στυγμᾶν*, to mark, brand, deriv. of *στυγμᾶ*, *στυγμᾶτος*, puncture, brand, mark, deriv. of *στυγμᾶ*, to prick, brand, mark]: a term employed in the literature of the Roman Catholic Church to denote the miraculous impression upon certain saints of marks similar to the five wounds of Christ (*stigmata*) or of the crown of thorns. Remarkable instances are those of St. Francis of Assisi (Sept. 15, 1224) and Veronica Giuliani (1694). Many persons, among whom was St. Catharine of Siena, are said to have felt at regular intervals the pain of such wounds, but without any external mark. See Görres, *Die Christliche Mystik* (1854), and Imbert-Gourbeyre, *Les Stigmatisées* (Paris, 1873).

Revised by J. J. KEANE.

Stiles, EZRA, D. D., LL. D.: clergyman and author; b. at North Haven, Conn., Dec. 15, 1727; son of Rev. Isaac Stiles, minister at North Haven; graduated at Yale College 1746; studied theology; was ordained a Congregational minister June, 1749; was tutor at Yale College 1749-55; engaged in a series of researches with an electrical apparatus sent to the college by Dr. Franklin, and made the first electrical experiments in New England; preached for a short time to the Stockbridge Indians 1750; studied law; was admitted to the bar 1753, and practiced two years in New Haven; pronounced a Latin oration in honor of Franklin on the occasion of his visit to New Haven, Feb., 1755; was pastor of a church at Newport, R. I., 1755-77; was inaugurated president of Yale College June 23, 1778; acted also as Professor of Ecclesiastical History after 1780; delivered lectures on scientific subjects; was author of a *History of Three of the Judges of King Charles I.* (Hartford, 1794) and *An Account of the Settlement of Bristol, R. I.* (Provi-

ance, 1750), and an unfinished ecclesiastical *History of New England*. D. at New Haven, May 12, 1795. His daughter married Dr. Abel Holmes, who published his *Life* (1798) and edited *The Family Tablet* (1798), containing poems by members of the Stillicho family. Revised by H. P. Fournier.

Stilicho, *stil'ikō*; general; son of a Vandal in the Roman service. He was born about 359; grew up in the camp, and developed such eminent talents that the Emperor Theodosius gave him his niece Serena in marriage; made him commander-in-chief of the whole military force of the Western empire, and appointed him guardian to the young Honorius. After the death of Theodosius in 395 A. D., Stilicho was the actual ruler of the Western Roman empire; he married his son to Placidia, the daughter of Theodosius, and his daughter, Maria, to the Emperor Honorius. The earlier part of his career was mostly occupied by rivalries with Rufinus, guardian of Arcadius, who had received the Eastern Roman empire, and the feud ended with the assassination of Rufinus. In 400, when Alaric invaded Northern Italy, Stilicho brought together in haste the legions which were stationed in Britain, Gaul, and all along the northern frontier of the empire; defeated Alaric first at Pollentia, then at Verona, and drove him out of Italy. But on the withdrawal of the legions from the frontiers immense swarms of barbarians gathered under Radagaisus, invaded Italy in 406, and besieged Florence. Stilicho attacked them and routed them completely; Radagaisus was put to death and his troops were sold as slaves. At the court, Olympius, a eunuch, succeeded in turning the mind of the young emperor from his gratification. While Stilicho was encamped at Bologna, a number of his friends were put to death at Pavia. In the camp Stilicho's friends demanded that he should march immediately against Pavia and punish Olympius; and when he hesitated they rebelled against him. He fled from the camp and took refuge at Ravenna, where he was murdered Aug. 23, 408. The principal events of his life have been celebrated in verse by the poet Claudian.

Still, JOHN, D. D.; bishop; b. at Grantham, Lincolnshire, England, about 1543; educated at Christ's College, Cambridge; took orders in the Church of England; became faculty Margaret Professor of Divinity at Cambridge 1579; held livings in Suffolk and Yorkshire; became prebendary of Westminster 1573, master of St. John's College, Cambridge, 1574 and of Trinity College 1577; archdeacon of Sudbury 1577, prolocutor of the convocation 1589, and Bishop of Bath and Wells 1592. D. at Wells, Feb. 26, 1607. He was the author of *A Ryght Pythie, Pleasant, and Moeve Comedie, intituled Hammer Gurton's Needle, played on the Stage not longe ago in Christes Colledge in Cambridge. Made by Mr. S. Noaster of Arts*, etc. (London, 1575). This piece, abounding in low humor, supposed to have been written as early as 1565, was long considered the first extant English comedy, but that rank is now assigned to Udall's *Ralph Royster Doyster*.

Stillingfleet, EDWARD, D. D.; bishop and controversial writer; b. at Cranbourne, Dorsetshire, England, Apr. 17, 1635; educated at Cambridge; took a fellowship 1653; entered holy orders; became rector of Sutton in 1657; preacher at the Rolls, London, 1654; rector of St. Andrew's, Holborn, London, and lecturer at the Temple 1665; prebendary of St. Paul's 1667 and of Canterbury 1669; chaplain to Charles II. 1670; dean of St. Paul's 1677, and Bishop of Worcester 1680, holding also several other ecclesiastical preferments. His ranks among the foremost of English polemics, his life having been an almost uninterrupted controversy with Roman Catholics, Nonconformists, and Socinians. He was characterized by unrivaled learning and a sincere love of truth. Many of his works have been frequently republished in different forms. The most important are *Irenicum, a Weapon-salve for the Churches Wounds, or the Divine Right of Particular Forms of Church Government, Dissolved and Examined* (1661); *Origines Sacre, or a Rational Account of the Christian Faith as to the Truth and Divine Authority of the Scriptures and the Matters therein contained* (1663); 9th ed. 1707; *A Rational Account of the Grounds of the Protestant Religion* (1665); *Discourse Concerning the True Reason of the Sufferings of Christ* (1669); *Discourse Concerning the Idolatry Practised in the Church of Rome* (1671); *Unconformity of Separation from the Church of England* (1681); *Origines Britannice, or Antiquities of the British Church* (1685); *The Doctrine and Practice of the Church of Rome Truly Represented* (1686); now ed. by W. Cunningham, Edinburgh, 1837; 3d ed. 1831—

a standard work; and *Discourse in Vindication of the Doctrine of the Trinity* (1697). He was so benignant that he was widely called the "beauty of holiness." D. at Westminster, Mar. 27, 1699. See memoir in his *Collected Works* (6 vols. fol., 1719). Revised by S. M. JACKSON.

Stillingia [Mod. Lat., named in honor of the English botanist Dr. Benjamin Stillingfleet (1702-71)]; a genus of euphorbiaceae from shrubs and herbs. The U. S. has several species. *Stillingia sylvatica*, queen's-delight or queen's-root, is an herb of the Southern states whose root has a good reputation as an antisyphilitic remedy. The tallow-tree of China (*S. sebifera*) is naturalized in the southern parts of the U. S. It is a beautiful tree, and from its seeds the Chinese extract large amounts of a white tallow-like fat, very useful for candles. The wood is hard and is a good substitute for box. The leaves give a black dye.

Revised by L. H. BAILEY.

Stillman, WILLIAM JAMES; painter, journalist, and critic; b. at Schenectady, N. Y., June 1, 1809; graduated at Union College, New York, 1848. He studied landscape-painting under Frederick E. Church and in France, exhibiting at the National Academy of Design in New York 1851-59. His most noted picture is the *Promission of the Peace*, painted in 1858. (See Emerson's *The Adirondacks*.) He was art editor of the *New York Evening Post* in 1853-54, and again thirty years later. In 1855 he founded, in connection with John Dupard, *The Oregon*, a monthly art journal in sympathy with the views of Ruskin and the Pre-Raphaelite brotherhood. In 1852 he visited Austria on a secret political mission for Kosuth. He was U. S. consul at Rome 1861-65, and in Crete 1865-69. Since then he has lived mainly abroad as correspondent of *The Times* in Greece and in Italy. He has given much attention to and has written controversially about Greek art and archaeology, particularly the cyclopean (Pelagic) constructions, which he has extensively explored. His principal works are *The Crete Insurrection of 1866* (New York, 1874); *The Hecatomnia and the Late Uprising* (London, 1877); *On the Track of Olympus*, embodying also an essay on the so-called Venus of Melos (Boston, 1889); also *The Acropolis of Athens*, a valuable collection of photographs (London, 1870).

Stills: See DISTILLATION.

Stillwater: city (settled in 1845); capital of Washington co., Minn.; on the St. Croix river, at the head of Lake St. Croix, and on the Chi. and N. W., the Chi., Mil. and St. P., the Chi., St. P., Minn. and Om., the St. P. and Duluth, and the Wis. Cent. railways; 16 miles N. E. of St. Paul, 25 miles E. N. E. of Minneapolis (for location, see map of Minnesota, ref. 9-P). Originally the settlement was on a small plain, slightly above the level of the lake, and surrounded by graceful bluffs; but with the growth of the city the plain has been surrendered to business houses and manufactories, and the bluffs are adorned with handsome residences. The city is 30 miles above the junction of the St. Croix and the Mississippi rivers, and, with regular lines of steamers communicating with Dubuque and St. Louis, claims to be at the head of Mississippi river navigation. Stillwater is the business center of the great St. Croix lumber region, which extends north over large portions of Minnesota and Wisconsin. It contains many large sawmills, with an aggregate daily capacity of over 500,000 feet, and a capital of \$3,000,000. During the summer several hundred million feet of logs are here formed into rafts to be towed by steamers to sawmills on the Mississippi. Although lumbering has always been the principal business, other industries have sprung up, and there are several flour-mills and feed-mills, grain elevators, foundries and machine-shops, carriage and wagon factories, and agricultural-implement works. There are 16 churches, 14 public schools, public library, 2 Roman Catholic convents, a hospital, 2 national banks with combined capital of \$500,000, 2 savings-banks, 1 daily, 6 weekly, and 3 monthly periodicals, and the State penitentiary. Pop. (1880) 9,055; (1890) 11,200; (1894) including suburbs, 18,960.

HARRY R. DANIEL.

Stilt: See ALTRA STILIA.

Stilt: any bird of the genus *Himantopus* (family Recurvirostridae). They are related to the avocets, and are distinguished by the excessively long legs, the straight, slender bill, which is slightly compressed, the feet with the middle and outer toes connected by a small web and destitute of a hind toe, and projection of the tail beyond the wings. There are some half dozen species, inhabitants of various

parts of the world. One is found in America, and ranges from the northern parts of the U. S. to Paraguay. Its total length is about 14 inches, of which the bill forms 3 inches, and the tail also 3 inches; the tarsi are about 4 inches in length, and rather longer than the tibiae; the color is a glossy black on the head above, the neck behind, the back, and the wings; white on the head in front of and behind the eyes, and beneath; the bill is black, and the legs red. It not only dwells by the seacoast, but is found far inland, at least on the lakes and rivers of the western parts of the U. S. The stilts generally associate together in flocks of twenty or thirty. They prefer muddy flats with reedy margins. They breed in the U. S., and make nests of grasses, etc. They lay generally four eggs; these are relatively large and of a yellowish or ochraceous color, with dark-brownish blotches and lines. According to Coues, on the ground, whether walking or wading, they move gracefully and with measured steps; the long legs are much bent at each step (but only at the joint), and planted firmly and perfectly straight. When feeding, the legs are bent backward at an acute angle at the heel-joint, to bring the body lower. They feed mostly on aquatic insects, as well as the eggs and young of fishes, and small fishes. Revised by F. A. LUCAS.

Stilton Cheese: See CHEESE.

Stimpson, WILLIAM, M. D.: naturalist; b. at Cambridge, Mass., Feb. 14, 1830. He devoted himself principally to the description of invertebrates. He was naturalist of the Ringold and Rodgers expedition to the North Pacific Ocean, later was curator of the Chicago Academy of Science, and lost all his collections, MSS., etc., in the great fire of 1871. Later he superintended the dredgings of the U. S. Coast Survey in the Strait of Florida. Among his works are *Testaceous Molluscs of New England* (1851); *Marine Invertebrates of Grand Manan* (1854); *Prodromus Descriptionis Animalium Evertibratorum* (1857-61, containing a part of the invertebrates collected on the Ringold and Rodgers expedition); *Notes on North American Crustacea* (1859-71); *Crustacea and Echinodermata of the Pacific Shore* (1857); and *Crustacea Dredged in the Gulf Stream* (1871). D. at Ithaca Mills, Md., May 26, 1872. J. S. K.

Stimson, FREDERIC JESUP: novelist; b. at Dedham, Mass., July 20, 1855; graduated at Harvard in 1876; was admitted to the bar, and in 1882, under the pseudonym *J. S. of Dale*, published *Guerndale*, a novel of college life. In 1884-85 he was assistant attorney-general of Massachusetts. Other novels are *The Crime of Henry Vane* (1884) and *The Residuary Legatee* (1888). He has also published a number of law-books, the most important of which is perhaps *American Statute Law* (1886). H. A. B.

Stimulants [from Lat. *stimulans*, *stimulantis*, pres. partic. of *stimulare*, urge, goad on, deriv. of *stimulus*, a goad]: those agents which increase functional activity of the various organs of the body, more particularly in connection with the respiration, circulation, and nervous system. Such are, pre-eminently, strongly nourishing hot food if it can be digested; if it can not, then alcoholic or etheral potions, ammoniacal solutions, heat, strychnine, etc.

Stimulus: that which excites or stimulates; used in physiology and psychology for any influence from outside which causes a reaction of the muscles in movement or of the attention.

Sting-fish: the greater weever (*Trachinus draco*). See TRACHINIDÆ.

Sting-ray: any ray of the genus *Trygon* (family *Trygonidae*), a group of elasmobranchs belonging to the order *Raiiæ*. These fish have the body rhombic and moderately broad, the skin smooth and without tubercles, the nasal valves coalescent into quadrangular flaps, the teeth flattened, and the tail long, tapering, destitute of a true fin, and armed with an elongated spine (sometimes with two) compressed from before backward, and with teeth or serratures at each side directed downward. These spines are the "stings" which have insured the popular name to the forms in question. There are about thirty species found in almost all tropical and temperate seas, and much dreaded on account of the wounds which they inflict with their spine-bearing tail. They can whip the tail around with great ease and transfix the incautious intruder with the spines. Tetanus is sometimes the result, but the wound is a physical injury solely and not the result of poison. One species (*Trygon centrura*) is quite common along the eastern coast of the U. S. See also TRYGONIDÆ. Revised by F. A. LUCAS.

Stinkhorn Fungi: the *Phallaceæ*, a family of fetid gastromycetous fungi numbering ninety-two species, most of which are tropical. The plants are filamentous saprophytes, growing in soil which is rich in decaying organic matter. The spore-fruits are roundish or egg-shaped bodies resembling PUFF-BALLS (q. v.), which develop at or beneath the surface of the ground and whose spore-bearing tissue (*gleba*) emerges from the peridium by the elongation of the sterile base (see figure). The fetid odor attracts flies and other insects, to which the spores adhere, thus securing their distribution. Several species occur in the U. S., one of the most common being the *Ithyphallus impudicus* (see figure), which is from 5 to 10 inches high, with a white or pinkish base (*volva*), a white, hollow, loosely cellular stalk, and a conical, reticulated pileus bearing black spores. Species of *Dictyophora*, *Mutinus*, and *Simblum* are common in the U. S. CHARLES E. BESSEY.

Stinkhorn (*Ithyphallus impudicus*) reduced one-half, with a young spore-fruit at the side.

Stinkstone: any one of certain marbles or limestones which on being struck emit the smell of sulphuretted hydrogen. The British islands abound in stones of this character and of various geological ages, some of them useful building-stones.

Stinkwood: the hard, durable wood of the *Ocotea bulbata* (family *Lauraceæ*) and related plants, found in South Africa. The wood is handsome and valuable, but has a disagreeable smell even when seasoned. *O. foetens*, a tree of the Canaries, has wood of a vile odor, but other members of this widespread genus are of pleasing fragrance. The name is also applied to a species of *Cassia*.

Stipple-engraving: See ENGRAVING.

Stirling: town of Scotland; capital of Stirlingshire: on the Forth; 35 miles N. W. of Edinburgh (see map of Scotland, ref. 11-G). It contains a fine old castle, situated on a basaltic hill, with steep precipitous sides toward the W. and rising to a height of 340 feet above the plain. The town and its vicinity are rich in historic associations, and contain many objects of interest. Tartans, shawls, rope, soap, leather, and malt are extensively manufactured, and an important trade both on the river and by rail is carried on. Stirling unites with Dunfermline, Culross, Inverkeithing, and Queensferry in sending one member to Parliament. Pop. (1891) 16,974.

Stirling, JAMES HUTCHISON, M. D., LL. D.: philosopher; b. in Glasgow, Scotland, June 22, 1820; took the course in arts and medicine at Glasgow University; for a short time practiced as a surgeon in New South Wales; abandoned practice in 1851 and went to Germany to continue philosophical studies; is the author of *The Secret of Hegel, being the Hegelian System in Origin, Principle, Form, and Matter* (2 vols., 1865); *Sir William Hamilton, being the Philosophy of Perception* (1865); *Jerrold, Tennyson, Macaulay, and other Essays* (1868); *As Regards Protoplasm* (1869); *Philosophy and Theology*, Gifford lectures (1890); *Darwinianism: Workmen and Work* (1894); and the translator of Dr. Albert Schweigler's *Handbook of the History of Philosophy* (1867). Dr. Stirling is an opponent of Haeckel and Huxley on biological theories.

Stirling, Sir THOMAS, of Ardoch: soldier; b. in Scotland about 1735; became a captain in the Royal Highlander July, 1757; served under Abercrombie at Lake George 1758, and Amherst at Lake Champlain 1759, at the siege of Niagara, and the invasion of Lower Canada 1760; was stationed in 1765 at Fort Chartres, Ill., whence he marched to Philadelphia 1766; became lieutenant-colonel 1771, colonel 1779, and major-general Nov., 1782; served throughout the war of the Revolution; took part in the battles of Long Island, Fort Washington, Red Bank, Brandywine, and Springfield; was made a baronet and lieutenant-general 1796, and full general Jan. 1, 1801. D. May 9, 1808.

Stirling, Sir WILLIAM: See MAXWELL.

Stirlingshire: a county of Scotland, bounded by the counties of Perth, Clackmannan, Linlithgow, Lanark, and Dumbarton, and forming the border land between the Highlands and the Lowlands. Area, 447 sq. miles, of which about two-fifths is under cultivation. The western part of the county is mountainous, and rich in iron, coal, and freestone. The highest peak is Ben Lomond, 3,192 feet above the level of the sea, near the foot of which lies the beautiful Loch Lomond. Agriculture, cattle-breeding, mining, and the manufacture of cotton and woollen goods, chemicals, etc., are pursued with success. The iron-works at Carron in this county are among the largest in the country. There are also extensive iron-works at Falkirk, where also three annual fairs, called *trysts*, the largest in Scotland, are held for the sale of horses, cattle, sheep, and wool. Stirlingshire is rich in historic associations, and boasts of many battle-fields, the chief of which are Stirling Bridge, Falkirk, Rannochburn, and Kilcree. Pop. (1891) 118,021. The county sends one member to Parliament. County-town, STIRLING (q. v.).

Stille, William: clergyman, educator, and author; b. in Virginia in 1680; educated in England, where he studied theology and took orders in the Church of England 1731; became in that year master of the grammar school of Williams and Mary College; chaplain of the Virginia House of Burgesses 1735, and president of Williams and Mary College and rector of Henric parish from 1752 to his death at Williamsburg, Sept. 27, 1755. He was a brother-in-law of Peyton Randolph, and author of a *History of the First Decades and Settlement of Virginia* (Williamsburg, 1747; 2d ed. 1753; new ed. New York, 1866). It traces the history only to 1624, has been by some critics censured as inelegant in style, but is admitted to be accurate and faithful, and the work is of the greater value since the materials on which it was based were destroyed by fire.

Stjernehjelm, styern'yel'm, Geroik: statesman, scholar, and poet; b. in Dalarna, Sweden, in 1598. He was the son of a poor miner named Margareta, but on entering school assumed the name of Göran Lölje. His early education was obtained at Vesterås. After filling various Government positions he was appointed by Gustavus Adolphus lecturer in the school at Vesterås. Afterward he was ennobled by the king, and assumed the name by which he is known in literature. He was court poet to Queen Christina and high in favor, but afterward fell under suspicion and was disgraced. D. in poverty 1672. His principal works are the didactic poem *Hercules*, written in hexameters; *Bröllops besvär* (*Wedding Vexations*) (Remembrances of Wedding Vexations), a humorous lyric poem, also in hexameters; and three so-called ballets—*Parnassus triumphans*, *Den fängne Cupido* (The Captive Cupid), and *Freda Af*—the first of which is like a modern opera, the others like the contemporary English masques. He is called the father of Swedish poetry. Before him there is a condition of absolute confusion in form. By his use of new meters, and particularly of the alexandrine, which he introduced into Swedish literature, he established a standard for his successors, who regarded him in form and language a model of artistic perfection. His poetical works were published at Upsala, 1850. See SWEDISH LITERATURE.

WILLIAM H. CARPENTER.

Stout: See EMMET.

Stobæus, Joannes [so called from his birthplace, Stobi, in Macedonia]: an author assigned to the end of the fifth century of our era. For the instruction of his son, Septimius, he made a collection of sayings on various subjects from about 300 Greek authors, and these quotations have become of great interest, as in most cases the works from which they were taken have perished. They are arranged in two separate works—*Anthologion* and *Eclogæ*—both edited by Meineke, the former in 4 vols. (1855-57), the latter in 2 vols. (1869-72). There is a new critical edition of both, under the common title *Anthologia*, by Wachsmuth and Henze (Berlin, 1894), of which the third volume appeared in 1894.

Revised by R. L. GILBERTSON.

Stockbridge: town: Berkshire co., Mass.: on the Housatonic river, and the N. Y., N. H. and Hars. Railroad; 5 miles N. of Great Barrington, 17 miles S. by W. of Pittsfield (for location, see map of Massachusetts, ref. 2-C). It is noted for picturesque mountain scenery, includes the beautiful Lake Mahomet, and has numerous villas, chiefly occupied during the summer by citizens of New York. Originally called Housatonic, the place was the chief residence of the wife of Indians of the same name, also called

Stockbridge Indians, who were Christianized in the eighteenth century by the labors of John Sargent, Timothy Woodbridge, and the celebrated Jonathan Edwards, to whose memory a monument has been erected here. The village, numbering 460, removed after the Revolution to Madison co., N. Y., afterward in the vicinity of Green Bay, Wis., and subsequently resided near Port Lawrenceville, Kan. Stockbridge was the native place of several eminent persons, including Catherine M. Sedgwick, Mark Hopkins, Cyrus W. Field, Henry M. Field, D. D., and Judge Henry B. Brown, of the U. S. Supreme Court. It contains the villages of Stockbridge, West Stockbridge Center, Curtsville, and Glendale, eight public schools, a public library (founded in 1822), an academy, woollen-mills, paper-mills, saw-mills, grist-mills, and sawmills, and a national bank with capital of \$200,000 and surplus of \$150,000. It was incorporated in 1789, and in 1894 had an assessed valuation of \$2,940,497. Pop. (1880) 2,377; (1890) 3,132.

HENRY M. FIELD, mayor of the "Village."

Stockbridge, Henry: lawyer; b. at North Hadley, Mass., Aug. 11, 1822; graduated at Amherst College in 1845; studied law in Baltimore, and was admitted to the Maryland bar in 1848. During the civil war he took an active part in favor of the Union; in 1864 was a member of the Legislature, and drafted the act by which a constitutional convention was convened for the abolition of slavery in Maryland; was a member of that convention, took an active part in its proceedings, exerted himself to secure the adoption of the constitution framed by it, and defended it before the court of last resort. He instituted and conducted a successful issue in the Federal courts proceedings by which were annulled the indentures of apprenticeship by means of which the effect of the emancipation clause was sought to be evaded, and thus secured the unfetterment of more than 10,000 colored children in the State. He edited for years the Fund publications of the Maryland Historical Society, of which he was vice-president. D. May 11, 1903.

Stock-dove: a European wild pigeon, *Columba oenas*, named from its habit of nesting in hollow stocks or tree-stumps, although it often builds in rabbit-burrows, etc. It is gray, with a purplish breast, scarlet eyes, orange bill, and red toes and legs. It is some 14 inches long. The young birds are prized as food.

Stock Exchange: an association of brokers in shares, bonds, or other securities of corporations, nations, states, counties, or municipalities, and in negotiable certificates representing commodities of trade. Until the decade 1880-90 the last-mentioned instruments were not regularly dealt in by stock exchanges. The Petroleum and Mining Exchange of New York city was, however, in 1885, expanded into an exchange for stocks, oil, and mining shares, and the older New York Stock Exchange shortly afterward admitted to regular trading on its board the so-called "pipe-line certificates" of the petroleum market, and later certificates of deposited silver bullion, through which the price of silver might be made a convenient speculation. Grain contracts for future delivery have also been dealt in regularly in the Consolidated Stock and Petroleum Exchange, but neither these nor the pipe-line certificates on the New York Stock Exchange became in any degree important features of the institutions.

Membership Regulations.—Membership in a stock exchange is usually limited, and as, in a number of exchanges, a "seat" is the property, not only of an active broker, but also of his heirs or assigns, the privilege represented by it possesses a marketable value. Memberships in the New York Stock Exchange have sold as high as \$34,000 (price reached in 1885), and as low as \$15,250, the record of 1896. Sales were made in the first quarter of 1895 at \$15,000. The purchase of a seat from a previous incumbent does not of itself entitle the buyer to the privilege of trading on the floor. He becomes a member only after formal application, and by the approval of the committee on admissions. On the London Stock Exchange the applicant for membership must be recommended by three members of at least four years' standing, who severally bind themselves to pay \$300 to the applicant's creditors, in case he be declared a defaulter within four years after his admission. No foreigner is eligible unless he shall have been naturalized for two years. In the Paris Stock Exchange the *agent de change* (see below) is ineligible unless a Frenchman. He must be proposed by his predecessor in membership (or that predecessor's heirs or proxies), and must be formally approved by the governing body of the exchange and the Minister of Finance.

Most stock exchanges place a limit on the number of members. On the New York Stock Exchange the limit is 1,100, a number reached after a considerable increase in 1869, when a successful rival, the Open Board of Brokers, was absorbed by consolidation of membership. In New York the Stock Exchange member frequently acts as solicitor of investment business—advertising extensively—as general banker and promoter, and as executor of orders on the floor. These functions are separated in London, where a customer usually gives his order to a broker in the exchange membership, through whom the “jobber,” also a member of the exchange, is employed; the Stock Exchange forbids all its members to advertise. By the constitution of the Paris Bourse, its members, the *agents de change*, number only sixty; but stock-exchange business in Paris fell largely from the first into the hands of *coulissiers* or outside brokers, who frequented the outer corridors of the Bourse and traded as though members of a regular exchange. The strife between the *coulissiers* and the *agents de change* is bitter and historic. The *coulisse* was repeatedly suppressed by the courts and the police, and was driven at times to other quarters of the city. In 1859 individual *coulissiers* were heavily fined, but their business, under the generic name of the Petite Bourse, flourishes to this day. Trading on the larger Bourse in recent years has been also carried on by the head clerks of the *agents de change*, each agent being allowed two such clerks with privileges of the exchange.

Discipline and Rules.—Stock exchanges are invariably governed by strictly enforced by-laws, covering rules for general management, mutual arrangement and enforcement of contracts, and requirement of personal business honesty and good behavior. On the New York Stock Exchange an insolvent member is suspended until he has settled with his creditors, and may be readmitted only on proof of such settlement and on the formal vote of the committee on admissions or, if rejected by them, on appeal to the general governing committee. Suspension or expulsion is also fixed as penalty for (1) the making of fictitious sales; (2) the making of fictitious or trifling bids or offers; (3) the buying or selling of securities for a less commission than that fixed in the by-laws; (4) “obvious fraud”; (5) refusal to comply with any other regular provision of the by-laws. The London Stock Exchange’s by-laws impose suspension or expulsion as penalty for violation of any Stock Exchange rules or regulations; for failure to comply with the committee’s decisions; and for “dishonorable or disgraceful conduct.” A declared insolvent also ceases to be a member. The *agent de change* in Paris is subject to discipline, under the institution’s by-laws, whenever he “does not confine himself strictly to his duties,” or if he “introduces into his operations or into the collection of his dues any innovations that may be injurious to the public weal or to the interests of the company.” The penalty is left wholly discretionary with the governing board or “syndical chamber.” It may fine, censure, or suspend a member, but for expulsion may only submit its recommendation to the Minister of Finance. This recommendation is, however, usually final.

“Listing” of Securities.—In nearly all stock exchanges no security can be dealt in on the floor unless it has been officially admitted by the committee appointed for the purpose. Securities may also be expressly excluded from trading by vote of this committee. The only exception to this privilege of exclusion, in European stock exchanges, is the public stock of the nation to which the exchange belongs. In London an explicit Stock Exchange rule forbids trading in public loans raised by nations at war with Great Britain. For the “listing” of new securities on the New York Stock Exchange certain formalities are prescribed. The applicant company must show to the committee on stock list that the shares or bonds in question were regularly issued, and that they have been actually marketed. A general financial statement at a date not too far distant must accompany the application. In the case of shares, the securities must be registered with a trust company satisfactory to the stock exchange. In the case of bonds, evidence must be submitted that the mortgage was properly drawn and properly recorded in every county touched by the enterprise. These stringent provisions were the result of numerous frauds and “over-issues” of securities in the earlier history of American stock speculation.

The competition of the Consolidated Exchange after 1885 led to some change in sentiment among the New York Stock Exchange authorities. A few years after that date the New York Exchange governors established a so-called “un-

listed department,” in which securities were admitted without the stringent provisions as to financial statement, registry of shares, etc. As a result, securities to an enormous aggregate value were admitted to official trading, when the investing public was left in total ignorance of the financial status of the enterprises. These securities soon became the chief center of active and reckless speculation. Although the Stock Exchange generally repudiates responsibility for the character and good faith of securities dealt in upon its floor, it has lately been generally admitted that the influence of these “unlisted securities” was demoralizing and harmful. Retroactive legislation against such securities was impracticable, but in Feb., 1895, the governing committee of the exchange adopted a resolution which marked an important change of policy. A very great amount of securities of insolvent companies were certain, later on, to be subject to reorganization. In such cases the new securities issued in the adjustment of the corporation’s debt must apply for admission to the Stock Exchange. The governing committee’s resolution stipulated that all such applications must be accompanied by a full and complete income report for the year preceding, by a detailed balance sheet, and by a civil engineer’s report on the physical condition of the property. The resolution also went much further, and officially “recommended” to all corporations, whose securities were already admitted to trading, the publication, at least fifteen days prior to an annual meeting, of a faithful and detailed income account and balance sheet for the year. Although not mandatory, this declaration of general policy was regarded as highly important in the struggle of investors to obtain complete and frequent financial statements from corporation directors.

Method of Business.—All stock exchanges provide an open hall where brokers may personally buy from or sell to one another, for their own account or that of customers, such securities as are admitted to trading. A regular commission, which is a fixed percentage usually on the par value of securities bought or sold, is established for all such trading. Members are forbidden under penalty to accept a less commission. On the New York Stock Exchange the regular minimum commission is one-eighth of 1 per cent. on outside orders, one thirty-second of 1 per cent. on orders given by fellow members, and one-fiftieth of 1 per cent. where a member has merely employed a fellow member to make the bargain, delivery being made to or by the real purchaser or seller. All commissions are reckoned on a security’s par value. In London the official Stock Exchange commissions vary according to the nature and face value of the security dealt in. On the stock of British and colonial corporations they range from 1s. to 5s. per cent.; on shares and bonds issued in the U. S. the commission is 1s. per \$100; on British and foreign government funds it is 2s. 6d. per cent. In Paris the official commission of an *agent de change* is one-quarter of 1 per cent.

The bids and offers made on the floor of the exchange, though made only personally, become official. A broker is forbidden under penalty to sell stock at a price lower than the best bid made in his hearing for the amount in question, or to buy at a price higher than the lowest offer. This is to prevent unfair “manipulation.” On the New York Stock Exchange the broker must deliver stock sold, and must pay for stock bought, by 2.15 p. m. on the day following the transaction. Since 1892 most of these transactions are settled through the Stock Exchange Clearing-house. (See below.) On the London Stock Exchange, and in the majority of exchanges in Europe, as well as some in the U. S., “settlements” between buyers or sellers are made at longer intervals. In London a contract made for purchase or sale of securities is settled by delivery of the securities and payment of the price at the next official settling day. These days occur at fortnightly intervals, or nominally twice a month, for general securities, and once a month for Government stocks. By mutual agreement, commonly on payment of a fixed percentage charge, the contract may be deferred or “carried over” to the next settlement. The Paris Stock Exchange and most other stock exchanges on the Continent deal “for the account” similarly to London. In all these exchanges cash transactions, closed on the spot, are admissible, though rare outside of British consols. In such cases, as may be seen by the daily quotations of British consols, the price for the “account” is usually higher than the price for “money” by a margin sufficient to cover the interest charge between the date of cash sale and the date of the next fortnightly or monthly settlement.

In all stock exchanges actual delivery of securities sold is required, the one apparent exception being in cases where mutually balanced contracts are entered through the stock exchange clearing-house. The courts have in this case, however, decided that the cancellation in no respect affected the intent to deliver, the enforceability of delivery, and the actual delivery of stocks as far as customers are concerned. The common assumption that trading in stock exchanges involves no real sale, purchase, or transfer, but is merely a species of gambling on differences, is wholly erroneous. This species of gambling is confined to the so-called "bucketshops," private concerns with no stock exchange membership, and which neither receive nor deliver actual securities, merely paying to customers or receiving from them the money balance due between the stock exchange price at the time of the fictitious sale or purchase and at the time the contract is closed. In the U. S. these institutions are illegal by the statute of most States, and are at intervals raided by the police as common gambling-houses.

Stock-exchange Clearing-house.—The clearing-house for stocks is the most recent development in the machinery of stock exchanges. It is a natural outgrowth of the bank clearing-house (*q. v.*), and serves a similar purpose. Its fundamental principle is to offset contracts by one broker, to deliver securities, with contracts entered upon by the same broker to receive the same securities. If A has purchased 1,000 shares of stock from B, and has sold 1,000 shares of the same stock to C, the stock exchange clearing-house returns a balanced sheet to A, who thereupon neither receives nor delivers any of the stock, the double transaction being settled by the delivery of the 1,000 shares by B to C. Or if A has bought 1,000 shares from B and sold 600 to C, the clearing-house so arranges that B shall deliver 400 shares to A and 600 to C, no deliveries being made by A. By an ingenious book-keeping system, this principle is extended to the entire membership of the exchange, and as such, active broker is apt to trade daily on both sides of the account in many securities, the economy in expense and labor is enormous. This system was first introduced in the Handelskammer at Frankfurt in 1867. It was found that through its employment the necessary transfers of securities were reduced more than 90 per cent. The Berlin Exchange adopted the system in 1869, Hamburg in 1870, Vienna in 1879, London in 1876, some of the U. S. exchanges between 1880 and 1887, and the New York Stock Exchange in 1892. The last-named institution, following and perfecting the plan of the Consolidated Stock Exchange of New York, added a system of money clearings, through which the checks due by brokers in settlement were mutually offset, so far as the two sides of any broker's account balanced, at the clearing-house. It is estimated by officers of this clearing-house that the saving in checks drawn for brokers' settlements, under this system, has in the New York Stock Exchange alone averaged \$400,000,000 per month. The system of money clearings has not been adopted in Europe, except, in a modified form, by the London Stock Exchange. The stock exchange clearing-house has received more full and complete discussion in *The Political Science Quarterly* for June, 1903.

History.—The trade of brokers, in the sense of professional buyers, sellers, and lenders on security, using for the purpose their own money or that of customers, is very ancient. Such trade was carried on in the Roman Forum during the days of the republic. The use for this purpose of the porticoes of the adjacent temples of Minerva and Mars Ultor is mentioned frequently by Martial, Juvenal, and other Latin writers, and their references assume a long-established institution. The brokers of that period, however, were hardly distinguishable from the bankers and money-lenders of the Middle Ages. The money-broker or money-changer, transacting much the same business as the money-broker do to-day, was older as representative of a distinct profession, and indeed followed early international commerce as a necessary accompaniment. In the later Middle Ages exchanges for the transaction of general business were established, usually by national or municipal governments, and took the place of the temple porticoes and public markets commonly used at the beginning of the Christian era. The Royal Exchange in London, founded under Elizabeth by Sir Thomas Gresham, was of this character, and was suggested by similar institutions already established in some of the German commercial cities. But these were not stock exchanges, and were never used as such except when,

in the infancy of stock-trading, a part of the general market space was used by brokers in securities.

The term broker is used in English statutory law as early as 1285, but apparently refers there to a species of pawn-broking business only. In 1694 an act of Parliament defines brokers only as dealers in "merchandise and wares." There is no evidence that the stock-broker in the modern sense became a factor in trade until the great movement for the creation of limited government debts at the close of the seventeenth century, followed a few decades later by the incorporation of the East India Company and the South Sea Company in London, and of the Mississippi Company in Paris. The shares of these corporations were offered for public purchase, and advanced enormously in value. Here the South Sea Bubble burst in 1720 the stock-poly had become a feature in English society, and both he and his peculiar professional slang were frequently in the literature of the period.

The stock-broker's business was long confined either to the Royal Exchange in London or, later, in the coffee-houses of the adjacent Change Alley. In 1691 the London Stock Exchange was founded in Chapel Court, where it has continued ever since. A public exchange for brokers was established in Paris as early as 1694, but stock-jobbing began only with John Law's Mississippi Bubble of 1720. It was suppressed by governmental edict in 1726 and in 1764, both actions being provoked by the great demoralization in values caused by currency inflation. The present Bourse was founded early in the nineteenth century, and was first occupied in 1806. Contrary to usage elsewhere, the expense of its construction was paid by the city. As an organized body of brokers, the New York Stock Exchange seems to have originated so early as 1792, solely "for the purchase and sale of public stock." Its meetings, however, were held only in coffee-houses, or in rooms of private buildings; first in an office at No. 47 Wall Street, and later in the old *Courier* and *Enquirer* buildings. In 1827 an upper room was chartered in the Merchants' Exchange, Wall and William Streets; from 1854 to 1857 a room over the Corn Exchange Bank was used, then a hall in a building on Beaver Street, the present exchange being completed and first occupied in Dec., 1863. The list of celebrated names among the speculators in the membership of the New York Stock Exchange includes Jacob Little, Samuel Ward, Cornelius Vanderbilt, William H. Travis, Charles Woerckoff, Daniel Drew, James Fisk, Jr., William H. Vanderbilt, and Jay Gould. Of these only the first mentioned, who flourished in the decade 1825-35, antedated the days of railway-share speculation. The Philadelphia Stock Exchange was founded at the opening of the century, and was for some time a more important institution than its New York rival. It has not kept pace with the New York Exchange, however, and, though trading actively in many of the securities dealt in at New York, devotes itself largely to specialties, notably, since 1890, to stocks and bonds of street-railways in various quarters of the Union. Philadelphia is the headquarters for the so-called traction stocks of New York, Baltimore, Philadelphia, and other cities. The Boston Stock Exchange—a much more recently founded institution—deals especially in securities of railways in New England. The Chicago Stock Exchange is dwarfed by the much larger concentration of grain-dealing in that city. Its dealings are chiefly restricted to shares and bonds of the elevated and surface railways of Chicago, Baltimore, New Orleans, and other cities possess also stock exchanges doing a still more limited business in securities of local enterprises. There are stock exchanges in all the principal commercial cities of Europe, and in many of the smaller municipalities. The most important institutions, outside of those already mentioned, are the stock exchanges of Berlin, Hamburg, Frankfurt, and Vienna.

Stock-exchange Phraseology.—Trading in stocks has for nearly two centuries been characterized by a set of terms and phraseology peculiar to itself. Of these the most familiar are the following: A "bear" is a market operator working to cause lower prices. A "bull," conversely, is working for higher prices. Both of these terms come in colloquial literature at least as old as England's South Sea speculation of 1720. The bear is usually said to be "short" of stocks. The origin of this more modern term is plain, and signifies that the operator has sold stocks which he does not yet own, for delivery at a fixed future date. The price may or may not be lower than previous recorded quotations. Usually he resolves his payment, at current prices, on the spot, and

in modern stock exchanges he also makes his delivery of stocks on the spot. But the stock thus delivered is borrowed from real holders, to be repaid when the "short" seller "covers"—that is to say, when he buys outright in the market to close his contracts. The bull is commonly "long" of stocks in a speculative way. This term signifies that he buys the stock and pays for it in money on the spot, but borrows the money for payment. When he sells his stock, at a profit or otherwise, he repays the loan. It often happens, therefore, that when the bear is borrowing stocks and the bull borrowing money, the one is simply lending to the other. Sales by the bulls are currently called liquidation. Stocks are said to be "carried" when a banker advances money to the bull speculator, retaining the stocks as security for the loan. The "carrying rate" naturally varies, therefore, with the rate of money and the demand for stocks. "Pools" are combinations of operators devoting their joint resources to the manipulation of a single security or group of securities. The manipulation is usually directed by one member of the pool. Contracts for such purpose have in some cases been recognized as legal by the courts, but appeal to law is rarely made, and bad faith, such as the "selling out on his associates" by one member of a "bull pool," is not easily proved against the offender. A "put" is a contract drawn by a capitalist or broker and sold at a specified sum to a speculator, in virtue of which the speculator may, within a fixed period, deliver the stock to the issuer of the put and be paid for it at a stipulated price. The buyer of a put is of course usually a bull, and buys the put to guard himself against losses on a possible decline. A "call" is the converse of a put. Its issuer contracts to sell to the buyer of the call, at or before a stipulated date, a certain amount of a certain stock at a fixed price. The bear buys this to guard against unexpected advances. A "spread" or "straddle" combines the features of both put and call, contracting at the option of its buyer to deliver to him or receive from him a fixed amount of securities named, the limits of price being set as many points apart as the situation, in the view of the issuer, will justify. All of the contracts described are generally classed as "options" or "privileges." A "wash sale" is a transaction in stocks wherein buyer and seller do not permanently transfer the securities at all, but work in a common interest to create semblance of activity and affect prices. In most stock exchanges "wash sales" are forbidden under heavy penalty, but they are difficult of detection and undoubtedly play a large part in current stock transactions. Two expressions in stock-exchange dialect, frequently used in cable dispatches, are peculiar to London. "Contango," a word probably derived from the continental expression for "contingent," refers to the rate or percentage charged an operator long of stocks for carrying over his account to the next fortnightly settling-day. (See above, under *Methods of Business*.) "Backwardation" is an etymological barbarism describing the premium, if any, charged to a short operator for permitting him to defer delivery from one settling day to the next. Its equivalent on the New York Stock Exchange is the premium charged in the "loan crowd," where actual owners of stocks are lending the shares to bear operators desirous of making present deliveries.

Statistics.—Transactions on the New York Stock Exchange are more carefully recorded and tabulated than in any other similar institution. The statistics of its business will therefore give a fair idea of the trading which passes annually on a great stock exchange. For the calendar year 1894 the following figures of actual sales have been compiled:

STOCKS AND SHARES.	Par value.	Market value.
Shares *.....	\$4,821,876,020	\$3,094,942,769
Railway bonds.....	339,950,250	248,987,506
U. S. Government bonds.....	4,345,400	5,220,460
State bonds.....	10,929,900	4,441,015
Bank stocks.....	527,985	924,507

* Total number of shares sold, 49,075,032.

The year 1894, however, being a period of great financial depression, is not a fair year to select as representative of investment and speculation. Even in 1893 the shares sold on the New York Exchange aggregated 80,977,839, of a par value of \$7,550,440,205, and a market value of \$4,550,260,916. The maximum year's record of the Stock Exchange in the several kinds of securities is as follows: Shares (number), 116,307,271 in 1883; railway bonds, \$660,659,400 in 1885; Government bonds, \$112,571,850 in 1879; State bonds, \$26,-

571,260 in 1882. It is generally estimated by brokers that sales of 200,000 to 300,000 shares a day are a fair average in active times. In a period of market excitement trading runs far beyond this average. The extreme high point was touched in the summer of 1887, when one day's total ran above 1,000,000 shares, the volume of business being so great that the Stock Exchange authorities were never able to compile its figures, even approximately.

LITERATURE.—The literature of this subject is not rich. The most complete legal and historical discussion will be found in J. R. Dos Passos's *Treatise on the Law of Stock-brokers and Stock Exchanges* (New York, 1882). The *Report of the British Royal Commission on the origin and methods of the Stock Exchange* (London, 1878) is full of valuable data. G. R. Gibson, of New York, has written several light but readable monographs on the various European exchanges. Various memoirs, chiefly of little value, have been published to narrate episodes of stock-exchange adventure. The most thorough and philosophical discussion of the financial questions involved in the subject is that of Robert Giffen, statistician of the British Board of Trade, in his *Stock Exchange Securities* (London, 1877). The numerous books and pamphlets on *How to Avoid Losses in Wall Street*, etc., are worthless and mischievous. Annual reports of the exchanges are usually limited to lists of officers, committees, and members. Valuable information as to the functions of stock exchange trading at earlier periods may be obtained from Walter Bagehot's *Lombard Street* (London and New York) and Clement Juglar's *Crises commerciales* (Paris).

ALEXANDER D. NOYES.

Stockfish (from the German *stockfisch*): a name for cod-fish and related species salted and dried. The fishes are split from head to tail, and the vertebral column in part taken out; they are then thoroughly washed and rid of the blood; after the water has been drained off, they are put in large vats, salted, and heavy weights are imposed; they are next washed and brushed, and laid out on the sandy shore and rocks. Finally, they are combined in small heaps, and become ready for the market, this stage being indicated by the assumption of a floury whitish appearance, technically designated as the "bloom." Revised by F. A. LUCAS.

Stockholm: the capital of the kingdom of Sweden; beautifully situated at the outlet of Lake Mälär in the Baltic (see map of Norway and Sweden, ref. 11-G). It is divided into (1) Staden, the inner city, consisting of the islands of Stadsholmen, Riddarholmen, and Helgeandsholmen; (2) Norrmalm, the northern part, connected with the inner city by a magnificent bridge of granite; (3) Ladugårdslandet, now Östermalm, communicating W. with Norrmalm; (4) Kungsholmen, communicating E. with Norrmalm; (5) Södermalm, the southern suburb, connected with the inner city by two drawbridges; and (6) Saltsjö-bårne, comprising the islands of Skeppsholmen, Djurgården, Kastellholmen, and Beckholmen, which complete the picture of an island city cut up and traversed in all directions by water. In Staden, the most prominent building is the royal palace, one of the most beautiful in Europe (built 1697-1754), containing a rich library, the palace of the stadholder, the mint, the town-house, the church of St. Gertrude, Storkyrkan, the Finnish church. In the island of Riddarholmen stand the Riddarholm church, containing the royal tombs, among which are those of Gustavus Adolphus and Charles XII.; the new house of deputies, and the statue of Birger Jarl. The bridge which leads from the inner city across the Helgeandsholmen to Norrmalm is 380 feet long and 64 feet broad; on its eastern side extend the most beautiful promenades of the city, Strömparterren. This part of the city contains the Brunkberg Place, the Hay Market, and the Place of Charles XIII., surrounded on three sides by rows of linden-trees, on the fourth by the sea, and ornamented by the statue of Charles XIII.; the palace of the princes, the royal theater, the Hammer museum, the academy of fine arts, the academy of science with rich collections, the observatory, the national museum, and the Fersen Terrace, which offers a magnificent prospect. Ladugårdslandet contains the arsenal, the barracks, the veterinary school, the academy of arboriculture, and the Hedwig Eleonora church; the Kungsholmen, the Seraphim hospital the Carolinian institute, the garrison hospital; and close by are Mariaberg, the military high school, and Carlberg, the cadet school. In Södermalm are Mosebacken, which presents the finest view of the city, and the Catharine and Maria Magdalene churches. Södermalm and Norrmalm are connected by a railway which for bold-

ness in construction hardly has any equal in the world. The central depot in Norrmalm is a fine building, and next to the royal palace, the largest in the city. Burgundien is a stone line park of considerable size, the general resort for amusement and recreation of the city, occupying a peninsula—2 miles long and 1 mile broad—whose western boundary has been much improved by art. Communication between the various parts of the city is generally covered on by small steamboats which traverse the waters in all directions, with fixed routes and a cheap fare. The surroundings are rich in beautiful parks, palaces, and villas, of which the royal summer palace, Drottningholm, is the most noticeable. The city possesses excellent water-works. The industry is considerable, especially in manufactures of tobacco, leather, linen, and cotton fabrics, iron, sugar-refining, etc. Commerce is also considerable, though navigation is closed each year for about five months, during which the harbor is covered with ice.

The town was founded toward the end of the twelfth century by King Knut Eriksson, and given the rank of city in 1286 by Birger Jarl. In 1289 it was taken by Margarethe, Queen of Denmark. On Oct. 14, 1471, the Swedes under Sten Sture defeated the Danes at Brånksborg, close by Stockholm, and drove them out of the country; but in 1520 they again took the city under Christian II, and the Stockholm massacre took place; by the general rising which the massacre caused throughout the kingdom Gustavus Vasa succeeded in establishing himself on the throne. During the peaceful times of the nineteenth century the prosperity of the city, like that of all Sweden, has much increased. Pop. (1890) 557,997. Revised by M. W. HARRINGTON.

Stock'mar, CHRISTIAN FRIDRICH; diplomatist; b. at Cölnberg, Aug. 22, 1787; studied medicine, and became physician and confidential adviser to Prince Leopold of Coburg, and was very active in various diplomatic negotiations. He was the intimate friend of Prince Albert and Queen Victoria; received the title of baron. D. at Cölnberg, July 9, 1865. *The Denkwürdigkeiten aus den Papiere des Freiherrn Christian Friedrich von Stockmar*, edited by his son (Darmstadt, 1872), was translated into English, with the title *Selections from the Papers of Stockmar*, and contains many interesting illustrations of the interior working of English politics in its relations with the court. See Jastot, *Le Baron Stockmar* (Brussels, 1873), and Catherine von Bauer's *Memories* (Kug. teins, 1864).

Stockport, town; in Cheshire, England; at the confluence of the Mersey and the Tame; 6 miles S. E. of Manchester (see map of England, ref. 7-G). It is irregularly built on rugged and uneven ground across a gorge spanned by a viaduct of the London and Northwestern Railway; has a number of fine modern buildings, including a market-hall and a technical school, etc. It is an important seat of the cotton industry, and has also breweries, brass-foundries, iron-foundries, machine-shops, etc. Stockport was the site of a Roman station, and afterward of a Norman castle which was destroyed during the parliamentary war. It returns two members to Parliament. Pop. (1891) 70,231.

Stocks, a wooden apparatus formerly much used in different parts of continental Europe and Great Britain for punishing petty offenders and vagrants. It consisted of two heavy timbers placed one above the other, with corresponding notches made in each, and so arranged that when the upper timber, which was movable, was shut down in place and fastened, holes were formed in which the wrists of the offender were secured. There were sometimes other holes for the hands, and in some cases a hole for the head. Stocks were first introduced into England probably about the time of the Statute of Laborers, 33 Edw. III. (1359), which provided that they be erected in every town; and by subsequent statutes this punishment was inflicted for minor offenses of various kinds down to very recent times. In the U. S. they were used to punish slaves. Stocks may still be seen in some villages in England.

F. STURGEON ALLEN.

Stocks and Stock Certificates; in the U. S., the collective name for the shares or a number of shares of a concern (usually a corporation, or the fund employed in the carrying on of its business or enterprise. In Great Britain the aggregate amount of the capital invested in a concern is called stock when it is not divided into shares, but, with certain limitations, into any such amount as a purchaser desires. In Great Britain the term stock is also applied to money lent to a government, or the fund or obligation consisting of a capital

debt by the Government to individual holders who receive interest at a fixed rate. This latter kind of stock, however, is a variety of public bonds.

Method of issuing stock.—A concern, in issue stock, need not necessarily be a corporation, but most of the stock in existence is issued by corporations. The capital stock of business corporations is usually divided into equal parts, called shares, the ownership of which confers a proportional right in the management of the company and to its profits, and in its assets upon dissolution. The amount of the capital itself, the number of its shares, and the par value of each are entirely arbitrary, and are fixed by the charter. The par value of shares is usually fixed at \$100, and otherwise, with very few exceptions, either at \$25, \$50, \$1000, or \$1500. This matter is often regulated by statute. The ownership of shares is usually evidenced by a stock certificate issued to each stockholder, certifying in substance that he is the holder of a designated number of shares. These stock certificates are not essential to the ownership of the shares or to their transfer, but they are merely the tangible evidences of the ownership of the shares and of the rights and duties attending to the ownership. They are negotiable, as are other physical chattels.

Kinds of Stock or Shares.—The stock of a corporation is frequently divided into two or more classes, with different rights and liabilities. The most common kinds are *common stock*, which is stock which entitles the owners to an equal proportionate dividend of the corporate profits and assets, with one shareholder or class of shareholders having no advantage, priority, or preference over another; and *preferred stock*, which is stock which entitles the owners to dividends out of the net profits before, or in preference to, the holders of common stock.

Other less common forms of stock are *deferred stock*, the payment of interest upon which is expressly postponed until some other class of shareholders are paid a dividend; and (under Massachusetts law) *special stock*, which is a legal statutory kind limited to two-fifths of the actual capital of the corporation, subject to redemption at par after a fixed time, and upon which the corporation is bound to pay a fixed half-yearly sum or dividend as a debt. The holders of this stock are in no event liable for debts beyond the amount of their stock.

The term *watered stock* does not designate any special class of stock issued, but is used to designate any stock issued as fully paid up when any amount less than the whole amount has been paid; that is, it is stock which purports to represent, but does not represent in good faith, money paid into the treasury of the corporation or money's worth actually contributed.

In Great Britain and France there is frequently issued a class of stock called *founders' shares*, the ownership of which entitles the holders to take the profits after certain other dividends are paid. They are a sort of deferred stock, and sometimes acquire great value. The term *scrip* is there in common use to designate a written acknowledgment by a corporation that the holder will be entitled to certain shares of stock and a certificate thereof when unpaid installments are paid. Another kind of stock issued in Great Britain and unknown in the U. S. is *debenture stock*, the issue of which is provided in the Companies Act, and which is a charge on the net earnings and profits of the corporation.

Issue of Stock.—It is not essential to the existence and continuance of a stock corporation that any stock certificates should be issued, but when the right is exercised it must generally be exercised for the benefit of all. The two general methods of issuing stock are (a) in pursuance to an agreement of subscription, and (b) by way of disposing of a surplus, or, as it is commonly called, by way of a stock dividend. A subscriber need not necessarily pay his subscription before he becomes entitled to his stock certificates. The issue of stock, the amount of the shares, the terms upon which it may be issued, the capitalization of the corporation, etc., are generally regulated by statute. Stock must be issued in strict conformity to the provisions of the corporation charter, and the unanimous consent of the stockholders will not validate either an over-issue of stock or reduction of the capital stock, except in strict compliance with the provisions of statutes.

The Legal Nature of Stock as Property.—With few exceptions, the English courts and the courts of the U. S. have held shares of stock to be personally, and in the nature of a chose in action. Shares of stock at the common law are therefore not subject to attachment or execution; and

under the English doctrine they are held not to be goods, wares, and merchandise, within the meaning of the clause of the Statute of Frauds, which requires delivery, payment, or a memorandum in writing to make valid a contract for the sale thereof. The contrary doctrine is held in the U. S.

Transfer of Stock.—The right of transferring stock is incidental to its ownership; and, although the officers of a corporation can not take away the right of reasonable transfer, they may make reasonable regulations governing it. The mode in general use, and often prescribed by statute, is as follows: A book is kept by some designated officer, in which is registered each certificate of shares, and the name of the person to whom it is issued. In order to complete a legal transfer, the holder of the certificate must surrender it up to this officer, who thereupon issues a new one for a like amount to the assignee, and registers it in the transfer-book, and cancels the old record. To obviate the necessity of the personal appearance of the assignor to surrender his certificate, it is the universal practice to print upon the back of the certificate a power of attorney to be signed by the assignor, constituting the assignee an agent to make the surrender, and perform such other acts as may be necessary to procure the cancellation and receive a new certificate. This power of attorney is often made out with a blank left for the name of the agent, and the instrument signed or indorsed in this form is passed from hand to hand through many successive owners, until some one inserts his own name, surrenders the certificate, and takes a new one.

Most corporations require, either in their charters or by-laws, that stock shall be transferable only on the books of the company. It is generally settled that a transfer otherwise regular but not registered as required is valid, and passes the interest of the transferor as between the parties. Where the rights of third parties are involved, the decisions vary as to the effect of the transfer. Except in a few cases, as where the transferor is indebted to the corporation and holds stock which is subject to a lien, or where no surrender has been made of the certificate, a corporation can not refuse to register a transfer of the stock upon the demand of the proper party; and in case of refusal, the registration of transfer may be enforced by either of several remedies—an action in equity; according to the same authorities, mandamus to compel registration; and an action at law for damages.

In the case of forged transfers, a corporation is liable to the real owner, and must make good any loss which he has suffered, and the same is true in various other cases, where the facts of the case are such as to charge the corporation with notice of the equity of the real owner.

Negotiability of Stock Certificates.—Stock certificates are not, strictly speaking, negotiable instruments; but they are practically treated in great financial centers as though they possessed the quality of negotiability. They are pledged as well as sold, and are thus used to a very great extent as collateral security for loans. Although the by-laws of a corporation may require a surrender, cancellation, and re-issue to complete a transfer and to create a perfect legal title, in the U. S. the doctrine of estoppel is applied to such an extent as to protect a *bona-fide* purchaser of stock, in almost every instance, where he would be protected if he were purchasing a promissory note or other negotiable instrument; and the courts are constantly extending this application of the law of estoppel.

In Great Britain an entirely different rule prevails, and certificates of stock there are mere evidences of ownership of stock, and are not negotiable or quasi-negotiable. The purchaser is not protected against equities involved in the title of prior owners of the certificate, and can shut them off only by a transfer on the books of the company; and this rule is applied to certificates of stock issued by U. S. corporations and held by British subjects.

In the U. S., if the holder of a certificate signs a power of attorney in blank, then delivers the certificate into the possession of some person for a specific purpose, as for safe-keeping, and this person in violation of his duties fills up the blank and fraudulently surrenders the certificate, and procures another one to be issued to a *bona-fide* purchaser, it is very generally held that the real owner would be estopped by his act of indorsing in blank from setting up a claim against a *bona-fide* purchaser. In this way the substantial benefits of negotiability are secured.

For further information, see Cook on *Stocks and Stockholders*.
F. STURGES ALLEN.

Stockton: city; capital of San Joaquin co., Cal.; at the head of Stockton channel, which connects it with the San Joaquin river, and on the Southern Pac. Railroad; 50 miles S. by E. of Sacramento, the State capital, and 100 E. by N. of San Francisco (for location, see map of California, ref. 7-1b). The entire San Joaquin valley, the richest and most prolific section of country in the world, 300 miles long and 100 miles wide, with its numerous cities and towns, is tributary to the city as a commercial and shipping point. Stockton is well laid out; has paved streets, four public squares, embellished with semi-tropical plants and flowers, excellent transportation facilities by rail and water, electric street-railway, gas and electric lights, thorough sewerage, and a water-supply from artesian wells; and contains 20 natural gas-wells, with a daily flow of over 500,000 cubic feet. The average temperature is 40° in winter and 75° in summer, and the death-rate is the lowest in the State. The public buildings include a granite court-house, which cost \$300,000; the Hazleton Public Library, of marble, cost \$85,000; the State Insane Asylum, which cost \$600,000; and the county jail.

Churches and Schools.—The principal religious denominations are represented by substantial church edifices. The public-school system has a high school and 12 grammar-school buildings, property valued at about \$270,000, enrollment (1894) 2,788, and annual expenses over \$67,000. St. Agnes's convent and St. Joseph's Primary School, under the Sisters of St. Dominic, are model institutions, with buildings and grounds covering an area of three blocks. There are also a business college and normal institute and several private schools of high grade.

Finances and Banking.—The annual revenue is about \$245,000; tax-rate, \$1.75 per 100; bonded indebtedness, \$370,000. There are 5 banks: the First National, with capital and surplus of \$436,000; Farmers' and Merchants', \$400,000; Stockton Savings, capital and reserve \$475,000; Stockton Savings and Loan Society, capital \$500,000, deposits \$1,600,000; and San Joaquin Valley, capital and surplus \$250,000.

Business Interests.—Stockton is an important manufacturing city, containing extensive flour, woolen, lumber, and paper mills, agricultural-implement works, foundries, ship-yards, machine-shops, and terra-cotta works. It is the wheat center of the State and one of the principal wheat-markets on the Pacific coast.

History.—The city was laid out in 1849 by Charles M. Weber, who owned a large tract of land under a Mexican grant; first became important as a point of departure for gold-mining parties, and has since prospered as a commercial and wheat-distributing center. Pop. (1880) 10,282; (1890) 14,424; (1895) estimated, 18,000. J. M. REUCK.

Stockton, ALFRED AUGUSTUS, Q. C., LL. D.: Canadian publicist; b. at Stockholm, King's County, New Brunswick, Nov. 2, 1842; graduated at Mt. Allison College in 1864; admitted to the bar in 1868. He is an examiner in arts in Mt. Allison College, an examiner in law at Victoria University, president of the New Brunswick Historical Society, and registrar of the court of vice-admiralty of New Brunswick. He has been a member of the New Brunswick House of Assembly since Aug. 23, 1883. He has edited, with copious notes, Berton's *Reports of the Supreme Court of New Brunswick*.
NEIL MACDONALD.

Stockton, FRANCIS RICHARD: humorist; b. in Philadelphia, Apr. 5, 1834. After graduating from the Philadelphia high school, he applied himself to wood-engraving and to literature, contributing illustrations to *Vanity Fair* and other periodicals, and issuing a number of stories for children, such as *The Ting-a-Ling Stories* (1869); *Tales Out of School* (1875), etc. He was employed successively upon the *Philadelphia Post*, the *New York Hearth and Home* (1872), *Scribner's Monthly* (afterward *The Century Magazine*), and *St. Nicholas* (1873). The first of his books to attract general notice to him, as a humorist of a new and original vein, was *Rudder Grange* (1879). This was followed by *The Lady or the Tiger?* (1884); *The Late Mrs. Null* (1886); *The Casting Away of Mrs. Lecks and Mrs. Aleshine* (1886); *The Dusanles* (1888); *The Merry Chanter* (1890); and many others.
H. A. BEERS.

Stockton, RICHARD: jurist; b. near Princeton, N. J., Oct. 1, 1730; graduated at the College of New Jersey in 1748; admitted to the bar in 1754; became member of the executive council in 1768, and judge of the Supreme Court of the province of New Jersey in 1774. He attempted to effect a reconciliation between the colonies and Great Britain, and

to this and submitted to Lord Dartmouth in 1771 "an expedition for the settlement of the American Dispute," in which he proposed a plan of self-government for the colonies; but in 1776 he was chosen a delegate to the Continental Congress, and was one of the signers of the Declaration of Independence. In Nov., 1776, he was captured by a party of royalists, who threw him into prison in New York, where he was treated with great severity; his library was destroyed, and his lands laid waste; he was finally exchanged, but never fully recovered from the effects of the ill usage which he had received. D. at his home near Princeton, Feb. 28, 1781. In 1809 his statue was placed by the State of New Jersey in the Capitol at Washington.

Stockton, Richard Field: naval officer; son of Richard (1764-1829), jurist and U. S. senator; b. at Princeton, N. J., Aug. 20, 1795; studied at the College of New Jersey, but left to enter the navy as a midshipman Sept. 1, 1811; became a lieutenant 1814; negotiated in 1821 the purchase from African native chiefs of the territory constituting the republic of Liberia; took part in the extermination of piracy in the West Indies; surveyed the Atlantic coast of the Southern States 1822-24; became commander 1830 and post-captain Dec. 8, 1838; was flag-officer of the Ohio in the Mediterranean 1838-39; declined the secretaryship of the navy 1841; was an early advocate of a steam navy; superintended the construction of the ship Princeton, the first successful war-steamship, 1842; was chosen to carry to Texas the resolution of annexation 1845; proceeded to the Pacific as commander of the U. S. squadron on the coast of California Oct. 1845; took possession of California for the U. S. Government, and formed a provisional government 1846; resigned from the navy May 28, 1850; was U. S. Senator 1851-53; was nominated in 1856 for the presidency by the newly formed "American party," but the ticket was withdrawn before the day of election. D. at Princeton, Oct. 7, 1866. See his *Life, Speeches, and Letters* (1866).

Stockton-on-Tees: town; in the county of Durham, England; on the left bank of the Tees, 4 miles from its mouth, 11 miles E. N. E. of Darlington (see map of England, ref. B-H). A new town which has sprung up on the right bank of the river is known as South Stockton, the two being connected by an iron bridge of three arches built in 1787. The Tees is navigable for vessels of large tonnage up to the town, and the navigation of the river has been much improved. The town is well built, and has flour-mills and spinning-mills, breweries, blast furnaces, foundries, engine-works, and building-yards for iron ships, and carries on a considerable trade in wheat, coal, iron, and timber. The Stockton and Darlington Railway, opened Sept. 27, 1825, was the first railway to begin passenger traffic. Pop. of the parliamentary borough, returning one member, (1901) 68,803.

Stoddard, Charles Andrews, D. D.: editor; b. in Boston, Mass., May 28, 1833; educated at Williams College, New Church College, Edinburgh, Scotland, and Union Theological Seminary; pastor of Washington Heights church, New York, 1858-63; and since 1863 editor of *The New York Observer*. Dr. Stoddard has published *America Russia* (New York, 1861); *Spanish Cities* (1862); *Beyond the Rockies* (1864); and many sermons and pamphlets. C. K. R.

Stoddard, Charles Warren: poet and traveler; b. at Rochester, N. Y., Aug. 7, 1843; educated at New York and California. In 1864 he visited the Hawaiian archipelago, where he has since resided at various times, and to which his writings largely relate. These include *Poems* (1867); *South Sea Idylls* (1876); *Makahala: a Flight into Egypt* (1881); and *The Legends of Molokai* (1885). In 1872-78 he traveled extensively as foreign correspondent of *The San Francisco Chronicle*. In 1885-89 he was Professor of English Literature at the University of Notre Dame, Indiana, and subsequently lecturer on English literature at the Catholic University of Washington, D. C. H. A. REXES.

Stoddard, Richard Henry: journalist and poet; b. at Hingham, Mass., July 2, 1825; was taken to New York when a child; attended the public schools of that city; became a bookbinder in an iron-foundry; contributed poems to various periodicals and in 1849 privately printed *Printed Poems*, a small volume of poems, followed in 1852 by a larger volume. From 1853 to 1873 he held appointments in the New York custom-house and bank department; was literary editor of *The New York World* in 1860-70, and in 1880 became literary editor of the *New York Mail and Express*. Besides numerous contributions in prose and verse to periodicals, he

has published *Adventures in Fairy Land* (1853); *Songs of Nature* (1855); *Down and Country* (1857); *Life, Travels, and Books of Alexander von Humboldt* (1860); *The King's Roll* (1862); the story of *Little Red Riding Hood* in verse (1865); *The Children in the Wood*, in verse (1865); *Alexander Lincoln, a Harbinger Tale* (1867); *Palmers the Brave* (1869); *The Book of the East*, a collection of his later poems (1871); a collection of his *Poems* (1880); and *The Lion's Cub*, poems (1889). He has also edited many volumes. See *Stoddard's Poets of America*, pp. 57-59.

Revised by H. A. REXES.

Stoever, Martin Luther, Ph. D., LL. D.: scholar and editor; b. at Germantown, Pa., Feb. 17, 1820; graduated at Pennsylvania College, Gettysburg, 1838; was tutor in Pennsylvania College, 1839-40, afterward principal of its preparatory department, and Professor of Latin, History, and Political Economy until his death July 22, 1870. He was for many years secretary of the General Synod of the Lutheran Church and editor of *The Evangelical Quarterly Review*, in which he published an interesting series of *Reminiscences of Lutheran Ministers*; edited *The Literary Record* (1847-48); wrote biographies of Dr. Henry M. Muhlenberg (1856) and of Dr. Philip F. Mayer (1859), and a *Brief Sketch of the Lutheran Church in the United States* (1860), and had made extensive preparations for a fuller history of the same subject. Revised by H. K. JACOB.

Stoics [from Lat. *Stoici* = Gr. *Stoikoi*, liter., belonging to the Porch, deriv. of *Stoa Basileia*, the Painted Porch at Athens in which the Stoics were wont to gather]; an ancient philosophic school founded about 310 B. C. by Zeno of Citium in Cyprus (flourished about 290-260). He numbered among his immediate disciples Pericles of Citium, Aristo of Chios, Herillus of Carthage, and Cleanthes of Assos, who succeeded his master. Cleanthes was succeeded by Chrysippus of Soli, who refused the Stoic doctrines to something like a system, and he by Zeno of Tarsus. Other celebrated Greek Stoics were Diogenes of Babylon, Antipatros of Tarsus, Panaetius of Rhodes, and Posidonius of Apamea. Owing mainly to Panaetius, Stoicism found numerous disciples among the Roman nobility, and for centuries exercised a great and good influence upon the stronger minds of the empire. Among the Roman Stoics may be mentioned Q. Muscius Scaevola, L. Annæus Cornutus, A. Persius Flaccus, L. Annæus Seneca, C. Muscius Rufus, Epictetus, and the Emperor Marcus Aurelius.

Stoicism was an offshoot from Cynicism, Zeno having been at first a disciple of Crates the Cynic; but it dropped some of the most objectionable elements of Cynicism, and became a civilized philosophy. It was divided by its adherents into three parts—logic, ethics, physics—of which the last was held to be most important, although the second received by far the most attention. Indeed Stoicism, like all the post-Aristotelian philosophies of antiquity, was essentially ethical.

(A) Under logic the Stoics included dialectic and rhetoric, the former of which was in reality a theory of cognition. They attached great importance to what they called a criterion of truth, although they were never able to fix upon any that would satisfy them as absolute. Their theory of sense-perception was essentially the same as that of Locke, the sentient soul being considered as a *tabula rasa*, impressed or otherwise affected by external objects. Perception was followed by memory and conception. Their highest concepts (*τὰ γενικώτατα*), by which they replaced Aristotle's ten categories, were (Trendelenburg, *Kategorienlehre*, p. 220, seq.)—

1. *Υποκειμενα* substrata.
2. " *κατα* qualified (essentially).
3. " *κατα* *συμπερα* accidentally.
4. " " *απλα* *κατα* their relation.

The Stoics, in the matter of general terms, were nominalists, or, more strictly, conceptualists. Under dialectic they included grammar, in the development of which they did some very good work. See Lasebi, *Die Sprachphilosophie der Alten*, pt. II, pp. 25, seq.; Steinthal, *Gesch. der Sprache bei den Griechen u. Römern*, pp. 777-789.

(B) Under physics the Stoics included theology. They repudiated Aristotle's plurality of causes by a duality, viz., force and matter, inseparable, and conceived very much as they are by modern physicists. Everything, even God, contains both. Their physical theory was in the main that of Hæcætus (p. 8), even down to the notion of a peribolical *κόσμος* or return of the universe to primeval fire. At the base of all lies necessity or providence—a tenet perhaps borrowed

from Empedocles (*περί φύσεως*, line 1). With periodical conflagration, individual immortality (resurrection of the body) was of course incompatible. The individual, a mere temporary emanation, returns at last to his source.

(C) In their *ethics* the Stoics, if not what is now called altruistic, were essentially unselfish—that is, they rigidly maintained that the end of life was virtue for virtue's sake. What virtue was they found it difficult to define, their "living agreeably to nature" being very vague, not to say that they sometimes made nature mean human nature, sometimes universal nature. Man exists for society, for only in that is virtue possible. Virtue is sufficient for happiness; and pleasure, which naturally accompanies activity, is not to be sought for its own sake. The cardinal virtues are practical wisdom, courage, self-restraint, and justice (*φρόνησις, ἀνδρεία, σωφροσύνη, δικαιοσύνη*), and it requires the possession of them all to constitute the truly wise man, who is free and the equal of Jupiter himself. The Stoics drew a broad distinction between acts and motives, and made the moral quality of acts depend entirely upon motives. Man shall do that which is good independently of surrounding influences and circumstances, and, having done that which is good, he shall feel happy independently of the sufferings and misery which may result from his acts. Of the works of the Stoics only fragments remain, the most important of which is Cleanthes's splendid *Hymn to Zeus*, of which there is an English rendering in Francis Newman's *The Soul, its Sorrows and Aspirations*, and another in *The Radical* (Boston, 1867). The best and most complete presentation of the Stoic philosophy is in Zeller's *Philosophie der Griechen* (vol. iv., pp. 26–340). English translation, *The Stoics, Epicureans, and Skeptics* (London, 1869). See also Ravaisson, *Essai sur le Stoicisme* (Paris, 1856); W. W. Capes, *Stoicism* (London, 1880); H. W. Bann, *The Great Philosophers* (2 vols., London, 1882).

THOMAS DAVIDSON.

Stokes, Sir GEORGE GABRIEL, F. R. S.: mathematician and physicist; b. at Skreen, Sligo, Ireland, Aug. 13, 1819; educated at Bristol College; graduated 1841 as senior wrangler at Cambridge, and was elected to a fellowship in Pembroke College; and in 1849 was elected Lucasian Professor of Mathematics in that university; was elected to the Royal Society in 1851, and was awarded the Rumford medal of that society 1852; was secretary 1854–85, and was president 1885–90. From 1886 to 1893 he was member of Parliament for Cambridge, and in 1889 he was made a baronet. He contributed a report on hydrodynamics to the British Association in 1846, which contains many valuable investigations of his own, and several memoirs to the *Philosophical Transactions* on the dynamical theory of diffraction and the theory of fluorescence and phosphorescence, and has written papers in several scientific journals. In 1884–86 he delivered popular lectures on light at Aberdeen, which were published in 3 vols. (1887). His mathematical and physical papers have been reprinted (2 vols., 1880–83).

Stokes, WHITLEY: Celtic scholar; b. in Dublin, Ireland, Feb. 28, 1830; educated at Trinity College, Dublin; barrister in London; barrister in Madras 1862; connected with the law department of the Government of India 1864–82, rendering important service in the codification of the Anglo-Indian laws. His chief activity has been in the field of Celtic philology, where he is a scholar of great accuracy and wide acquaintance with the materials involved. He is the author of *Irish Glosses* (1860); *The Play of the Sacrament, a Middle English Drama* (1862); *Three Irish Glossaries* (1862); *Gwreans an Bys, the Creation of the World, a Cornish Mystery, with a Translation and Notes* (1864); *The Indian Succession Act* (1865); *Hindu Law-books, edited with Notes and an Index* (Madras, 1865); *A Cornish Glossary* (1870); *Goidelica* (2d ed. 1872); *The Old Welsh Glosses on Martianus Capella* (1872); *Life of St. Meriasek, a Cornish Drama* (1873); *Three Middle Irish Homilies* (1877); *On the Calendar of Oengus* (1880); *Togail Troy* (1881); *The Anglo-Indian Codes*, editor (2 vols., 1887–88); *Urkeitscher Sprachschatz*, in vol. ii. of Fick's *Vergl. Wörterb.* (1894).

Revised by BENJ. IDE WHEELER.

Stokes' Law: See FLUORESCENCE.

Stoke-upon-Trent: town; in Staffordshire, England; on the Trent; 16 miles N. of Stafford (see map of England, ref. 8–G). It is the capital of the Potteries district, producing earthenware, porcelain, encaustic tiles and pavements. Coal-mining and brick-making are also carried on, and engines, machinery, etc., are manufactured. Pop. of the parliamentary borough, returning one member, (1891) 75,352.

Stolz, stölts, FRIEDRICH: philologist; b. at Hall, in the Austrian Tyrol, July 29, 1850; studied at the gymnasiums of Hall and Innsbruck, and at the Universities of Innsbruck and Leipzig; teacher successively in the gymnasiums of Görz, Klagenfurt, and Innsbruck; since 1887 professor in the University of Innsbruck. He is the author of *Die zusammengestellten Nomina in den homerischen und hesiodischen Gedichten* (1874); *Die lateinische Nominalcomposition in formaler Hinsicht* (1877); *Beiträge zur Declination der griech. Nomina* (1880); *Studien zur lateinischen Verbalflexion* (1882); *Lateinische Laut- und Formenlehre* in Müller's *Handbuch der Alterthumswissenschaft* (1885; 2d ed. 1889); *Die Urbewölkerung von Tirol* (1886; 2d ed. 1892); *Historische Grammatik der lateinischen Sprache*, vol. i., *Einführung, Lautlehre, und Stammbildungslehre* (1894).

BENJ. IDE WHEELER.

Stomach [from Lat. *stomachus* = Gr. *στόμαχος*, throat, gullet, stomach, deriv. of *στόμα*, mouth]: the chief organ of digestion; the expansion of the anterior portion of the alimentary canal for the reception of food, its disintegration and solution, and the digestion of albuminoid matter. The stomach is situated on the left side of the body, below the diaphragm, behind and beneath the free ribs. Its lower extremity extends across the median line. It is a membranous bag or sac, capable of great distension by food and gas, but often flaccid and collapsed when empty. When full it is 12 inches long and 4 high. The oesophagus through its heart orifice, so termed because adjacent to the heart. The body of the stomach is beneath the ribs on the left side, and is termed the *fundus, cul de sac*, or *great pouch*. The *greater curvature* of the stomach is the lower, convex surface; the *lesser curvature* is concave and above. Food leaves the stomach through its lower orifice, the *pylorus* (Gr. *πυλωρός*, from *πύλη*, a gate), and enters the duodenum, the first section of the small intestine. The stomach has four coats: (1) The external serous layer, a reflection of the peritoneum, covering it at all points except the entrance of the nutrient vessels and nerves in the great and small curves. (2) The muscular layer, which has three separate sets of fibers—the longitudinal, the circular, and the oblique. These muscular bands, acting in different directions, propel the contained food from side to side of the cavity, aiding in its chemical disintegration by thorough admixture with gastric juice. This spiral movement is termed *vermicular* (worm-like), and also *peristaltic* (Gr. *περιστέλλω*, to surround or wrap up). (3) The cellular coat, consisting of loose areolar tissue, connects the muscular to the internal mucous layer. It is called also the sub-mucous coat and the vascular coat, as it contains the blood-vessels which supply the elaborate capillaries beneath the secreting glands of the mucous membrane. (4) The mucous coat is thick, especially at the lower or pyloric end, presents large longitudinal folds when the stomach is but partially filled or empty, which disappear when it is distended. Closely inspected, the mucous surface is found to

FIG. 1.—Section of oesophagus, stomach, and duodenum.

FIG. 2.—The muscular coat of the stomach.

FIG. 3.—The mucous membrane of the stomach, orifices of the glands; magnified 20 diameters (Sappey).

the blood-vessels which supply the elaborate capillaries beneath the secreting glands of the mucous membrane. (4) The mucous coat is thick, especially at the lower or pyloric end, presents large longitudinal folds when the stomach is but partially filled or empty, which disappear when it is distended. Closely inspected, the mucous surface is found to

be perforated by innumerable closely aggregated orifices of the gastric tubules. These are of two kinds: (1) the peptic glands situated in the cardiac and central parts of the organ, and (2) the pyloric situated at the pyloric end. The stomach is constantly lubricated by secreted mucus, which may become excessive in digestive disorders. Gastric juice is chiefly secreted after the ingestion of food. (See DIGESTION.) The stomach is intimately related to important adjacent viscera by both vascular and nerve connections. Its main artery, the gastric, springs from a common root with the hepatic and splenic arteries, and it also receives two branches of each of them. By branches of the sympathetic nervous system its functional activity is influenced by the health of each organ and part of the body; it receives the terminal branches of the pneumogastric nerve, which gives off branches controlling the action of the heart, lungs, and in

FIG. 4.—A peptic gland, magnified 100 diameters (Sappey).

a measure the larynx and pharynx. It is by these connections that gastric indigestion may cause palpitation of the heart, difficult and sighing breathing, irritability of the larynx, and hoarseness, and by reflex influence many morbid sensations in various parts of the body.

The most frequent diseases of the stomach are its functional disorders. (See DYSPEPSIA.) In addition to these milder and chronic conditions, the stomach is liable to acute and organic disease. Acute inflammation or gastritis is of rare occurrence, the result of violent mechanical or chemical irritation, swallowing corrosive poisons or putrid and acrid food. It is characterized by violent ejection of all food, gastric mucus, traces of blood and bile, by sense of local burning pain, feeble pulse, cold extremities, and collapse. Perforating ulcer of the stomach is a not infrequent disease in young women of anæmic character. The symptoms are pain in the stomach upon reception of food, its rejection, and occasional hæmorrhage when the ulcerative process has eroded a blood-vessel. Hæmorrhage from the stomach is termed *hæmatemesis*, and must be carefully discriminated from *hæmoptysis*, the spitting of blood from the lungs. Cancer of the stomach is a relatively common affection of old persons, particularly of the male sex. It often occurs in persons of cancerous family history, in others with no hereditary taint. When at the pylorus, food is detained in the stomach, and after a time is ejected in great quantity, mixed with mucus, blood, and many fungous products of fermentation. There is a local darting pain, and often a local indurated tumor felt at the epigastrium through the emaciated abdominal wall; the face is cachectic, the body wasted, strength fails, death comes by exhaustion. Extreme neuralgia of the stomach—gastralgia or gastro-dynia—may occur, dependent on deranged nerve-centers or rheumatic or gouty vice of the blood.

Revised by W. PEPPER.

Stomach-pump: a form of syringe which has a flexible tube, designed to be passed down the œsophagus into the stomach, after which water is injected through it into the stomach and then withdrawn by reversing the action of the syringe. The operation may be repeated until the stomach is thoroughly washed clear of its contents. The instrument is especially useful in removing poisons from the stomach. In case of insane persons, or where some disease of the mouth or œsophagus exists, artificial feeding is required, and is usually accomplished with a simple rubber tube. The same is used in the treatment of diseases of the stomach for the purpose of washing out that organ.

Revised by W. PEPPER.

Stomap'oda, Stom'apod, or Stomatop'oda [Mod. Lat.; Gr. *στόμα*, *στόματος*, mouth + *πόδος*, *ποδός*, foot]: a group of malacostracous crustaceans, embracing about sixty species of marine forms with elongate loose-jointed bodies. The carapax is small, having the last three thoracic rings free; the stalked eyes have a distinct ring; five pairs of feet are modified for maxillipeds, the second of these forming a strong pincer; and three pairs of thoracic feet, each of which is two-branched. The gills are borne on the abdominal feet. These characters mark the group off strongly from all other forms. They further differ from most crustaceans in that

they deposit the eggs in their burrows. The young, though large, are thin and transparent, and were long regarded as

Mantis shrimp.

belonging to different forms. The species, which are known as Mantis shrimps, and which belong to the single family *Squilla*, are all inhabitants of the warmer seas, a single species occurring as far north as Massachusetts. See Miers, *Ann. and Mag. Nat. Hist.* (1880); Brooks, *Challenger Expedition*. J. S. KINGSLEY.

Sto'mate [from Gr. *στόμα*, mouth]: a breathing-pore in the epidermis of plants, consisting of two elongated, somewhat curved cells, the guard-cells (*g* in figure), between which is a definite opening. When the guard-cells curve away from one another, as they do when the atmosphere is moist, the slit between them is opened, permitting the free ingress and egress of gases. The stomates are always placed over intercellular spaces of the underlying tissues, an arrangement which permits an interchange of gases throughout the plant.

Stomates are found in some liverworts, where they are curious chimney-like structures, but in the nearly related mosses (where they are confined

Stomates of beet: a, top view, open; g, guard-cell; b, same closed; c, vertical transverse section, open; d, same closed, highly magnified.

to the capsules) they have essentially the same structure as in the flowering plants. In the fernworts they occur on the leaves and stems, and do not differ in any essential respect from those in the flowering plants. They rarely occur on submerged parts of plants, and in leaves which lie upon the surface of the water they are confined to the upper side. In ordinary leaves they are usually more abundant upon the lower side. In some, as in the compass-plants, they are about equally abundant upon both sides. The number of stomates on leaves varies very greatly. Weiss determined the number per square millimeter for the leaves of many species, and published the results in Pringsheim's *Jahrbücher für wissenschaftliche Botanik* (1865). A few of these are given below:

Olive (*Olea europea*), 625; hackberry (*Celtis occidentalis*), 616; black walnut (*Juglans nigra*), 461; lilac (*Syringa vulgaris*), 330; barberry (*Berberis vulgaris*), 229; golden currant (*Ribes aureum*), 145. In the foregoing, stomates occur on the upper side only; in the following they occur on both sides: sunflower (*Helianthus annuus*), upper, 175, lower, 325; cabbage (*Brassica oleracea*), u. 219, l. 301; pea (*Pisum sativum*), u. 101, l. 216; Indian corn (*Zea mays*), u. 94, l. 158; cottonwood (*Populus monilifera*), u. 89, l. 131; oats (*Avena sativa*), u. 48, l. 27.

In the development of stomates an epidermal cell undergoes division, usually into two unequal portions, and the smaller part is again divided in like manner. This may occur a third or even fourth time, when a last division into two equal parts (the guard-cells) takes place. These soon

become somewhat rounded and separate at the center by the splitting of the partition between them.

CHARLES E. BESSEY.

Stomatit'is: See MOUTH, DISEASES OF THE.

Stomatopoda: See STOMAPODA.

Stomat'idæ [Mod. Lat., named from *Sto'mias*, the typical genus, from Gr. *στόμα*, having a large mouth, deriv. of *σῶμα*, mouth]: a family of isospondylous fishes. The species are elongated and of a club-shaped form, tapering from before backward; the skin is naked, or covered with very thin and readily deciduous scales; opercular apparatus imperfectly developed and very oblique; mouth with a very deep lateral cleft; upper jaw with its margin formed by the supramaxillary as well as intermaxillary bones; teeth on the jaws acute, and often barbed; gill openings very deep and continuous below; branchiostegal rays numerous (twelve to seventeen); anal fin very far behind and small; caudal distinct; pectoral fins low down on the scapular arch, and narrow; ventral fins inserted far backward. The ovaries have oviducts, and consequently the eggs are discharged directly through them into the water. The family is composed of a few species, which are rather small (all being considerably less than a foot in length), and inhabitants of the open sea and deep water.

Stone [O. Eng. *stān* : O. H. Germ. *stein* (> Mod. Germ. *stein*): Goth. *stains*; cf. O. Bulg. *stēna*, wall, and Gr. *στῆν*, pebble]: in engineering, either natural or artificial rock suitable for use in foundations, walls, and piers. The natural sandstones, limestones, and granites furnish the greater part of all stone used in architecture and engineering. The essential qualities of a rock which renders it a good building-stone are strength and durability, while beauty and cheapness are desirable. The Egyptians quarried many very large stones for obelisks and for use in their temples, while from the earliest times stone-cutting has been a well-understood art. The cutting of dimension stones in the quarry by means of channeling-machines, introduced about 1870, has materially lowered the cost of many varieties of natural stone. See BUILDING-STONE for an account of the properties and methods of testing natural stone, and MASONRY for a description of the manner in which stones are laid together in buildings and engineering constructions.

Artificial stone consists of blocks or monolithic masses formed of materials which cement together. It is a combination of hydraulic cement, sand, crushed stone, pebbles, etc. Some varieties are of great value in districts where durable and cheap building-stone is not supplied by nature. The strength and durability of all varieties of artificial stone vary directly with the ultimate strength and hardness attainable by the hydraulic ingredients employed. An obvious means of improving their quality, therefore, is the employment of the highest grades of cement. Artificial stone may be made into blocks to be used as cut stone, or it may be built up into immense masses of any desired shape by moulding the different parts in place. The more important artificial stones are briefly described below. Most of these bear the names of their inventors.

CONCRETE (*q. v.*) is composed of hydraulic cement, sand, and broken stone or pebbles, and is much used in engineering construction. **Granolithic** is a trade-name for a combination of hydraulic cement and crushed granite (a granitic concrete), frequently employed for sidewalks and curbs, and for floors in stables, cellars, breweries, etc. **Béton-Coignet** is a combination of hydraulic cement, hydraulic lime, and sand, much used in France. The peculiarities are the substitution of hydraulic lime instead of part of the more expensive and stronger cement, and the small quantity of water used, and the thoroughness of the mixing. **Portland stone** is a name frequently given to a mixture of Portland cement and sand. The term Portland as applied to the stone, and also as applied to the cement of which it is made, was derived from the similarity of the artificial stone to the natural stone derived from the island of Portland, off the south coast of England. **McMurtrie stone** consists essentially of the Portland stone described above, in the pores of which are formed compounds of alumina with the fatty acids by the double decomposition of alum and a potash soap. The peculiar merit of this stone is that its power of absorbing water is decreased by the use of the alum and the soap. Absorbed water dissolves the salts of magnesia, lime, soda, and potash (of all of which there is always more or less in cement), and on evaporating leaves a white efflorescence on the surface which injures the appearance of the wall.

For this reason the ordinary artificial stones are in disfavor for architectural purposes. The **McMurtrie stone** has been used in Washington, D. C., to a limited extent, the window-trimmings of the National Museum and also the fronts of a few stores and dwellings being of this stone. **Frear stone** is composed of sand and Portland cement, to which gum shell-lac is added. The shell-lac adds to the early strength of the stone, but it is not certain that it adds to the ultimate strength. It was for a time much used in architectural work in the western parts of the U. S., but did not give satisfaction. **Ransome stone** is made by forming in the interstices of sand, gravel, or any pulverized stone a hard and insoluble cementing substance, by the natural decomposition of two compounds in solution. Sand and the silicate of soda are mixed in the proportion of a gallon of the latter to a bushel of the former and rammed into moulds. At this stage of the process the blocks or slabs may be easily cut into any desired form. They are then immersed, under pressure, in a hot solution of chloride of calcium, after which they are thoroughly drenched with cold water to wash out the chloride of sodium formed during the operation. In Great Britain grind-stones are frequently made by this process. **Sorel stone** has as its basis a cement formed by adding a solution of chloride of magnesium to the oxide of magnesium. The strength of this stone as well as its hardness exceeds that of any other artificial stone yet produced. This process was formerly used in making emery-wheels. Owing to the great strength of the cement only a comparatively small proportion is required. **Medusaline** is an artificial stone combining the peculiarities of the McMurtrie and Sorel processes. In one variety the inert material is sawdust and the product is used as fire-proofing.

IRA O. BAKER.

Stone: in Great Britain, legally a weight of 14 lb. avoirdupois; but other stones are in use, such as 24 lb. of wool and 8 of butcher's meat. In other European countries there are weights called stone differing in pounds avoirdupois, and chiefly employed for weighing wool, hemp, flax, and feathers, the stone for flax containing twice as many pounds as the one used for wool or feathers. In all the principal commercial states of Germany the stone (of flax) is the fifth of a hundredweight (centner = 100 or 112 lb.)—i. e. 20 lb. in Prussia and the Zollverein, Hamburg, Lübeck, and Bremen, 22 lb. in Austria, while in Sweden it is equivalent to 32 lb. The origin of this peculiar method of weight-measuring is rather obscure, and still more so is that of the different forms into which it has branched.

Stone (in pathology): See CALCULUS.

Stone, CHARLES POMEROY: soldier; b. at Greenfield, Mass., Sept. 30, 1824; graduated at the U. S. Military Academy in 1845; appointed a brevet second lieutenant of ordnance; served in the war with Mexico, and was breveted captain; constructed the arsenal at Benicia, Cal., and performed the duties of chief of ordnance of the division of the Pacific 1851-56; engaged in the banking business for a year in San Francisco; in 1857 was appointed by the Mexican Government chief of a commission to survey and explore its lands in Sonora and Lower California; was appointed Jan. 1, 1861, to organize and drill the District of Columbia militia for defense of the capital. Appointed colonel of the Fourteenth U. S. Infantry May 14, and a brigadier-general of volunteers May 17, he served under Gen. Patterson during the latter's operations in the Shenandoah in July. In Feb., 1863, he was placed in confinement in Fort Lafayette, New York harbor, and held until Aug. 9, when released, not only without charges being preferred against him, but without explanation of the cause of his arrest. In 1863 he served in the department of the Gulf; in 1863-64 was chief of staff to Gen. Banks; mustered out of volunteer service Apr. 4, 1864. He commanded a brigade of the Fifth Corps before Petersburg from Aug. 21 to Sept. 13, 1864, when he resigned from the army. He was in the military service of the Khedive of Egypt 1870-82; brigadier-general and chief of staff 1870; Ferik-Pasha 1873-83, a grade next below field-marshal; received numerous decorations and orders, and filled various confidential positions under the khedive. He was chief engineer for the erection of the Bartholdi statue of Liberty, New York. D. in New York, Jan. 24, 1887.

Stone, DAVID MARVIN: journalist and author; b. at Oxford, Conn., Dec. 23, 1817; was a merchant in Philadelphia 1842-49; obtained his earliest reputation as an author of poetry and light literature contributed to newspapers and magazines; became commercial editor of *The Journal of*

Commerce, New York, 1846; with William C. Prime purchased the paper in 1861, and a few years later became its editor-in-chief, which position he resigned in 1899, and of *Frank Forester*, which passed through more than thirty editions. D. in Brooklyn, N. Y., Apr. 2, 1899.

Stone, John S. 1823, D. D., clergyman, b. at West Stockbridge, Mass., in 1823; graduated at Union College in 1851; studied at the General Theological Seminary, New York, and took orders in the Episcopal Church 1856; was rector of churches at Edinfield, Conn., Frederick, Md., New Haven, Conn., Brooklyn, N. Y., Brookline, Mass., and of St. Paul's, Boston; lecturer in the Philadelphia Divinity School 1862-67; dean of the faculty of the Massachusetts Theological Seminary 1867-76. Besides several sermons and articles in periodicals, he published *Life of Bishop Griswold* (Philadelphia, 1841); *The Mysteries Unveiled* (New York, 1844; republished with title *The Christian Sacraments*, 1866); *The Church Universal* (1846), revised and enlarged as the *Living Temple*, 1899; *Life of Jesus Milner* (1848); *The Contrast, or the Evangelical and Trinitarian Systems Compared* (1853); *Lectures on the Christian Sabbath* (1867). D. at Cambridge, Jan. 15, 1892.—His son, JAMES KESE STONE, b. in Boston in 1840; graduated at Harvard in 1861; was ordained deacon and priest in the American Episcopal Church; professor (1863-67) and president (1867) of Kenyon College, Gambier, O., from which he received the degree of D. D. He was president of Hobart College, Geneva, 1868-69, but in 1870 entered the Church of Rome, becoming a Priest of the Order.

Revised by W. S. PERRY.

Stone, Lucy, reformer; b. at West Brookfield, Mass., Aug. 12, 1818; graduated at Oberlin College 1847; began to speak on woman's rights and anti-slavery in the same year; lectured through the U. S. and Canada to large audiences; helped organize the first national woman's rights convention at Worcester, Mass., in 1840; married Henry D. Blackwell in 1865; helped organize the New England Woman Suffrage Association in 1868 and the American Woman Suffrage Association in 1869, and was chairman of the executive committee of the latter for twenty years; established *The Woman's Journal* in Boston in 1870, and was its editor till her death, which occurred at Dorchester, Mass., Oct. 18, 1893.

Stone, THOMAS: a signer of the Declaration of Independence; b. at Pointon Manor, Charles co., Md., in 1743; was educated by a private tutor; studied law at Annapolis, and in 1764 began practice at Fredericktown. He was a member of the Continental Congress 1775-79, and advocated the establishment of an independent government, although at first instructed by the Legislature of Maryland to oppose it; the State receding from its opposition, he was one of the signers of the Declaration of Independence; was again elected to Congress in 1783, and was a member of the committee to draft a plan of confederation, and was appointed a delegate to the convention of 1787, but was unable to attend. D. at Fort Tabasco, Md., Oct. 5, 1787.

Stone, Age of: an archaeological term denoting the stage of development in which people used tools and weapons made of stone. It does not refer to general chronology, but to a period in the development of each race. Thus certain races of the South Sea Islands and extreme north have belonged to the stone age in the nineteenth century. It seems probable that in all parts of the world men have passed through this stage before making use of metals. (See BARREN, AGE OF.) In Europe the Stone Age is divided into two periods: the Palæolithic and the Neolithic. The remains of the former consist exclusively of flint, and roughly shaped by chipping into rude forms. The Neolithic implements include axes, batons, knives, etc. These are made of various stones, some finer specimens being of jade, and are often highly polished. See CHERT and LAKE-DWELLINGS. R. A. R.

Stone, Artificial: See STONE.

Stone-borer: any one of several bivalve molluscs belonging to several distinct families (*Pholidae*, *Gastropoda*, *Unionidae*, *Veneridae*, *Petriculidae*, and *Mytilidae*) which have the faculty of perforating stone. The boring is accomplished by the shell and by the rubbing of the foot sloughed with sand. Besides these molluscs, species of worms and earthworms also excavate stone, and to that extent may be called stone-borers. R. A. R.

Stone-chat: a bird, the *Protonotaria rubicola*. The male, in the breeding season, has the head, neck above, and back nearly black; the chin and throat black, and the neck on the

sides white; breast chestnut in front and lighter backward; the wing-coverts of the tertials white, but partly lost by the other coverts, which are blackish brown, edged with lighter brown; upper tail-coverts white, and tail-feathers blackish; tail and legs black. (Jewell.) The female is duller. The species is common in most parts of Middle Europe and Northern Africa. It is resident throughout the year in Great Britain, though mostly migratory in corresponding latitudes on the Continent. Its food is insects.

Stonecrop: the wall-pepper (*Sedum acre*). See WALL-PEPPER.

Stone-fly: any plecopteron insect of the family *Plecoptera*. See ECRONATOLOGY (*Plecoptera*).

Stone-fruits: a popular name for those fruits which are known in botany as drupes. Most of them belong to the genus *Prunus*, which includes plums, apricots, peaches, nectarines, and cherries. See DRUPE.

Stoneham: town (incorporated in 1725), Middlesex co., Mass.; on the Boston and Maine Railroad; 12 miles S. by W. of Boston (for location, see map of Massachusetts vol. 2-B). It is noted for its manufacture of shoes and leather, and contains a national bank with capital of \$50,000, a savings-bank, 6 churches, high school, 28 district schools, a public library, box-factory, machine-shops, and 2 weekly papers. In 1894 it had an assessed valuation of \$4,004,167. Pop. (1880) 4,580; (1900) 5,155. EIGHTH OF "INDEPENDENT."

Stonehenge [from Saxon *Stonhengest*, hanging stones]: a group of remains of rude-stone structures, standing on Salisbury Plain, 2 miles from Amesbury, Wiltshire, England. It is at present much defaced, but was composed somewhat as follows: At the center was a large slab of blue limestone, 16 feet in length, supposed to be an altar. Around this were nineteen granite posts, over 20 feet in average height, set in an ellipse. Around this was another ellipse of sandstone posts, bearing a transom or lintel of sandstone across the top. There seem to have been six of these triliths. Outside this ellipse was a circle of thirty rough pillars of granite, some 6 feet high. Outside of this there was a circle, about 100 feet in diameter, of thirty sandstone posts, 4 feet apart and 13 feet high. A horizontal course of stone, dovetailed and mortised to the top of the uprights and to each other, ran around this circle. Seventeen pillar-stones and six impacts retain their original positions. Without this circle there were a ditch and double mound of earth including an area of about 120 yards in diameter. Many sepulchral barrows are found in the vicinity. It was first mentioned in the twelfth century by Henry of Huntingdon and Geoffrey of Monmouth, whose account may be considered as giving the earliest beliefs with regard to the origin of Stonehenge. Numerous theories have been propounded, and Stonehenge has been attributed to the Phœnicians, Druids, Saxons, and Danes; but it is mostly regarded by later archaeologists as a burial-place of the people of the Bronze Age.

Stone Implements: See STONE, AGE OF; and INDUSTRY OF NORTH AMERICA.

Stone-lily: a crinoid having the form of a lily. See ECRINITE.

Stoneman, GEORGE, soldier; b. at Busti, N. Y., Aug. 8, 1822; graduated at the U. S. Military Academy in 1846, and entered the First Dragoons, which he joined at Fort Leavenworth, whence he conducted a supply-train to Santa Fé, N. M., where he became acting quartermaster of the Mormon battalion, which he accompanied to California in 1847. In Mar., 1855, he became a captain in the Second Cavalry, and served until 1861 mainly in Texas; was in command at Fort Brown in February, when he was ordered by Gen. Twiggs to surrender to the State forces, but refused to do so, and evacuated the fort. He was promoted to be major First Cavalry, May, 1861; served on the staff of Gen. McClellan in West Virginia; Aug. 19 was appointed brigadier-general of volunteers and chief of cavalry of the Army of the Potomac, which he organized and commanded during the Virginia Peninsular campaign of 1862; succeeded to command of Kearny's (first) division, Third Corps, on the death of the latter, and of the Third Corps Nov. 15, 1862; was promoted major-general of volunteers Nov. 29, 1862, and led his corps at the battle of Fredericksburg; commanded cavalry raid to Richmond Apr.-May, 1863; was chief of cavalry bureau July, 1863-Jan., 1864; in command of Twenty-third Corps Jan.-Apr., 1864; of cavalry corps department of Ohio Apr.-July, 1864, participating in the Atlanta campaign May-July, 1864; conducted a raid for the

capture of Macon and Andersonville and liberation of prisoners, but was compelled to surrender July 31, and held prisoner until Oct. 27; in temporary command of the department of Ohio Nov., 1864; in command of various districts and departments until mustered out of volunteer service Sept. 1, 1866; became colonel Twenty-first Infantry July 28, 1866; breveted colonel, brigadier, and major-general for gallant conduct; retired from active service Aug. 16, 1871. Resigned Sept. 15, 1882; Governor of California 1883-87. D. in Buffalo, N. Y., Sept. 5, 1894.

Stone-pine, Swiss: See CEMBRA PINE.

Stone River, Battle of: See MURFREESBORO.

Stoneware: See POTTERY AND PORCELAIN.

Stoneworts: the *Characeæ*, an order of lower plants, allied to the RED SEAWEEDS (*g. v.*) on the one hand and the

FIG. 1.—a, a stonewort (*Chara intermedia*), half the natural size; b, portion of stem, $\times 15$; c, cross-section of stem, $\times 15$.

Mossworks (*g. v.*) on the other. They are small, green aquatic plants with jointed stems, bearing whorls of leaves

FIG. 2.—a, leaf, bearing young sexual organs, $\times 15$; b, carpogone; c, coronula, $\times 80$; c, antherid; d, threads from interior of antherid, $\times 200$; e, antherozoid, $\times 600$.

(Fig. 1). Both stems and leaves are very simple, being often no more than a row of cells, but sometimes a cylindrical mass of cells. The sexual organs, which occur upon the leaves, consist of antherids and carpogones. The former are globular bodies (Fig. 2), which at maturity are hollow and contain a number of short-celled threads. Each cell contains a spiral antherozoid, which, escaping into the water, swims actively with a rotating motion. The carpogone consists of a central cell, the oöspere, which soon becomes covered by a layer of spirally twisted cells, the pericarp, surmounted by one or two rows of short cells, the coronula (Fig. 2, b, c). Fertilization takes place by the entrance of the antherozoid through the opening in the coronula, and its fusion with the oöspere, which then acquires a thicker wall. This ripened spore-fruit soon falls to the bottom of the pond, and after a period of rest germinates by sending out a jointed filament, which eventually gives rise to a branching plant again.

The stoneworts number about 150 species, which are distributed among five genera and two families, viz., *Nitella* and *Tolypella*, constituting the family *Nitelleæ*, and *Lamprothamnus*, *Lychnothamnus* and *Chara*, constituting the family *Characeæ*. In North America there are about sixty-two species, widely distributed in ponds and slow streams.

The best works on the *Characeæ* are T. F. Allen's *Characeæ of America* (New York, 1888); W. Migula's *Die Characeen in Rabenhorst's Kryptogamen Flora von Deutschland, Oesterreich und der Schweiz* (Leipzig, 1890); and A. Brann's *Fragmenta einer Monographie der Characeen*, edited by O. Nordstedt (Berlin, 1882).

CHARLES E. BESSEY.

Stonington: town (incorporated in 1658); port of entry; New London co., Conn.; on Long Island Sound, and the N. Y., N. H. and Hart. Railroad; 12 miles E. of New London, one of the county-seats (for location, see map of Connecticut, ref. 11-L). It includes the borough of Stonington, the villages of Old Mystic, Mystic, and Pawcatuck, and the farming region known as the Road district. The town has an excellent harbor, protected by a breakwater, and is in daily steamboat communication with New York. The principal industries are the manufacture of silk and cotton machinery, cotton and woolen goods, printing-presses, paper-cutters, spools for silk and thread, velvet and thread, boilers, and iron and brass goods. Stonington has a national bank with capital of \$200,000, a savings-bank, and a weekly newspaper. In Aug., 1814, the town was bombarded by a British fleet, but the people successfully resisted occupation. Pop. (1880) 7,355; (1890) 7,184.

EDITOR OF "MIRROR."

Stony Point: town; Rockland co., N. Y.; at the head of Haverstraw Bay; on the west side of the Hudson river, and on the N. J. and N. Y., the N. Y., Ont. and W., and the W. Shore railways; 42 miles N. of New York (for location, see map of New York, ref. 8-J). It is on a rocky promontory, which was fortified early in the Revolutionary war, was captured, strengthened, and garrisoned by the British, was retaken by the U. S. forces under Gen. Wayne in a night attack July 16, 1779, and soon afterward the fortifications were destroyed and the place abandoned. The summit contains a lighthouse and fog-bell tower. The house in which Benedict Arnold held his treasonable interviews was destroyed by fire in 1892. Remains of the fortifications are still preserved. Pop. (1880) 3,308; (1890) town 4,614, village 514.

Stop: in the organ, a series or set of pipes of similar tone and quality, tuned in regular gradation according to the order of the scale, and corresponding with the key-board either in the whole or a part only of its range. These stops are either simple or compound. A simple stop (as a diapason, flute, or trumpet) has only one pipe allotted to each key on the keyboard, but in a compound stop (as the sesquialtera or mixture) there are from two to five pipes for each key. The stops in a large organ are not only of various qualities of tone—soft, loud, delicate, bold, shrill, and the like—or imitations of the trumpet, violin, flute, etc., but are also distinguished by peculiarities of pitch, some stops giving the sound represented by the finger-keys to which they belong, others the octave or double octave below or above, while others are tuned in triple octaves above, and even in double and triple thirds and fifths, the whole combining and blending together with united effect, as if each key sounded only one richly toned pipe. The theoretical basis of this latter class of stops is explained in the article HARMONIC STOPS (*g. v.*). Organ-pipes are of two classes—flue-pipes and reed-pipes. The former are either metallic cylinders of

various forms and proportions, with a mouth and lip resembling those of the ordinary pitch-pipe, or are square wooden tubes projecting round on the same principle. The latter are chiefly metallo tubes of tapering form, provided with flexible reeds of brass or other metal, the vibrations of which produce a sound softer and more penetrating than that of the diaphragm. Among the flutes are the diapasons, principal, twelfth, fifteenth, second, and the compound stops; also the gamba, krumpholzer, and the various flute-stops. In the class of reed-stops the most prominent are the trumpet, trombone, horn, bassoon, clarinet, oboe, hautboy, and cor anglais. See *Organ and Pipe in music*.

Revised by DONALD ROCK.

Stoppage in Transit [*in transitu* = Lat., in passage]: in law, stopping goods while they are in transit, and resuming possession of them by an unpaid seller, who has parted with their possession. The seller is allowed to exercise this right upon discovering the insolvency of the buyer, on the ground "that the goods of one man should not be applied in payment of another man's debts." The rule originated in obscure cases decided during the latter part of the seventeenth century, and was adopted by the common-law courts "for the benefit of trade." *Balliford v. Jones*, 3 East 181.

By whom exercised.—This right has been regarded with much favor by the courts that they have permitted not only sellers, but persons in the position of sellers to exercise it; for example, an agent of the seller to whom the bill of lading has been issued, or a consignee, or an agent of the buyer who has himself paid, or is directly responsible for, the price. (British Sale of Goods Act, 1893, § 49.) A seller is deemed unpaid when he has not been paid in full, or when he has received a negotiable instrument as conditional payment, which has been dishonored or has been discredited by the insolvency of the parties liable thereon to the seller. Nor does it matter that the buyer has negotiated such paper. A buyer upon credit is bound to keep his credit good, if he would prevent the unpaid seller from exercising his right of lien or of stoppage in transit.

Buyer's Insolvency.—This is the basis of the right in question. If the seller knew of the buyer's insolvency when the sale was made on credit, there would be no equity in permitting him to stop the goods after deliberately parting with their possession in favor of the insolvent (*Pentecost v. Williams*, 20 Nev. 313); but the fact that the buyer was insolvent when the sale was made, if unknown to the seller, does not affect the latter's right. (*Benedict v. Schuette*, 12 Ohio St. 515.) A buyer who disputes the rightfulness of a particular stoppage of goods, by an unpaid seller, must prove that he was not insolvent when the goods reached their destination, and that he had not "afforded the ordinary apparent evidences of insolvency." A person is insolvent, within the meaning of the word in this connection, who has ceased to pay his debts in the ordinary course of business, or who is unable to pay his debts as they fall due, whether he has committed an act of bankruptcy, or become subject to insolvency proceedings or not.

Transit.—The rule upon this head was stated by Lord Esher, as follows: "When the goods have not been delivered to the purchaser or to any agent of his to hold for him otherwise than as a carrier, but are still in the hands of the carrier as such and for the purposes of the transit, then, although such carrier was the purchaser's agent to accept delivery as to pass the property, nevertheless the goods are *in transitu* and may be stopped. There has been a difficulty in some cases where the question was whether the original transit was at an end, and a fresh transit had begun. The way in which that question has been dealt with is this: Where the transit is a transit which has been caused either by the terms of the contract or by the directions of the purchaser to the vendor, the right of stoppage in transit exists; but if the goods are not in the hands of the carrier, by reason either of the terms of the contract or of the directions of the purchaser to the vendor, but are *in transitu* afterward in consequence of fresh directions given by the purchaser for a new transit, then such transit is no part of the original transit, and the right to stop is gone. So, also, if the purchaser gives orders that the goods shall be sent to a particular place, there to be kept till he gives fresh orders as to their destination in a new carrier, the original transit is at an end when they have reached that place, and any further transit is a fresh and independent transit." (*Bethell v. Clark*, 20 Queen's Bench Division 615.) Whether the delivery of goods on board a ship, chartered by the buyer, puts them into the

buyer's possession or not, or amounts to a final delivery at their place of destination, depends upon the intention of the parties, as disclosed by all the circumstances of the case. Goods are still subject to the right in question while in the carrier's or other custodian's possession, although they have reached the end of their transit, provided the buyer has not taken actual or constructive possession of them. For example, where the carrier retains or warehouses those subject to his lien for freight and charges, or where the buyer has rejected them; or where he has obtained delivery of a part only. If the delivery of part is made under such circumstances as to show an agreement to give up possession of the whole, or if the carrier wrongfully refuses to deliver the goods to the buyer, or if the carrier attorns to the buyer, that is, acknowledges that he holds the goods for the buyer, the transit is at an end.

Defeating the Right during Transit.—The buyer may defeat it by obtaining delivery of the goods before their arrival at the appointed destination. In Great Britain it seems to be immaterial whether delivery is obtained rightfully or wrongfully (*Whitehead v. Anderson*, 9 M. & W. 519; Sale of Goods Act, § 46 (2)); but there is authority in the U. S. for the view that this premature delivery must be obtained in good faith. (*Debs v. Ry.*, 58 Tex. 194.) He may also defeat it by a sale of the goods accompanied by the delivery of actual or constructive possession, but a sale without delivery will not affect it. A creditor of the buyer can not defeat the right by levying an attachment or execution upon the goods while in transit. Such a levy gives him no greater claim to the property than the debtor had; and, besides, the object of the right—to prevent the application of one man's goods to the payment of another's debts—is defeated against such a creditor. Constructive possession of the goods may be given by the transfer of the bill of lading. It follows that a transfer of the bill of lading to a bona-fide purchaser of the goods for a valuable consideration will defeat the right of stoppage in transit. It has even been held that such a transferee will get a clear title to the goods, although the right of stoppage had been exercised before the transfer, the goods being in transit still. (*Newhall v. Ry.*, 51 Cal. 344.) If the bill of lading is transferred by way of pledge, instead of by way of sale, the right of stoppage is subject to the rights of the pledgee.

How Exercised.—Either by taking actual possession of the goods or by giving notice of his claim to the carrier or other bailee in possession of the goods. When it is given not to the person in actual possession, but to his principal, as a ship-owner or a transportation company, it must be given at such a time and under such circumstances that, by the exercise of reasonable diligence, it may be communicated to the one in actual possession in time to prevent delivery to the buyer.

Consequences.—The seller does not rescind the sale by stopping the goods *in transitu*, but restores his vendor's lien. Upon his giving due notice to the carrier or other person in possession, it becomes the duty of the latter to redeliver the goods in accordance with the seller's directions, but at the seller's expense. After the goods are stopped, the purchaser or his assignee may regain them by paying or tendering the price. Under the British statute (§ 48), if the goods are perishable, or if the seller notifies the purchaser of his intention to resell, and the latter does not within a reasonable time pay or tender the price, the goods may be resold, and the original seller may recover from the original buyer any loss thereby occasioned. This seems to be the common-law rule. (*Tutill v. Skidmore*, 124 N. Y. 149.) The right of the seller who has stopped goods *in transitu* is similar to that of a pledgee, with power to sell at private sale in case of default.

FRANCIS M. BRIDGES.

Storage Batteries: See ACCUMULATORS.

Storer, DAVID HUMPHREYS, M. D.; naturalist; b. at Portland, Me., Mar. 26, 1804; graduated at Bowdoin College in 1825; devoted himself especially to natural history, and, besides contributions to scientific periodicals, published a translation from the French of Krieger's *Monera, Spores, etc., of Recent Shells* (Boston, 1837); *Ichthyology, etc., of Massachusetts* (1839); *Fishes of North America* (Cambridge, 1845); and *History of the Fishes of Massachusetts* (Boston, 1853, and, with plates, 1866). D. in Boston, Sept. 10, 1891.

Storer, FRANCIS HUMPHREYS, B. S.; in Boston, Mass., in 1832; graduated at the Lawrence Scientific School in 1835; was Professor in the Massachusetts Institute of Technology 1865-70; since 1870 Professor of Agricultural Chemistry in

Harvard University, and dean of the Bussey Institution; has contributed to scientific periodicals; was the American editor of Barreswill's *Répertoire de Chimie appliquée*, and has published *Alloys of Copper and Zinc* (1859); *Manufacture of Paraffin Oils* (1860); *First Outlines of a Dictionary of the Solubilities of Chemical Substances* (1863-64), and with Charles W. Eliot, *Manual of Inorganic Chemistry* (1869); *Manual of Qualitative Chemical Analysis* (1870); and *Agriculture in some of its Relations with Chemistry* (2 vols., New York, 1887).

Storer, HORATIO ROBINSON, M. D.: surgeon; b. in Boston, Mass., Feb. 27, 1830; educated at Harvard, where he received A. B. 1850, and M. D. and A. M. in 1853; was Professor of Obstetrics and Medical Jurisprudence in the Berkshire Medical College; has contributed largely to medical literature, and has published *Why not? A Book for every Woman*, which received the gold medal of the American Medical Association (1866); *Is it I? A Book for every Man* (1867); *Decrease of the Rate of Increase of the Population in Europe and America* (1867); *Nurses and Nursing* (1868); with F. F. Heard, *Criminal Abortion, its Nature, its Evidence, and its Law* (1868) and *Volunteer Sanitary Organizations as an Aid to Official Boards of Health* (1890). He was coeditor of *The Journal of the Gynecological Society of Boston* from 1869 to 1872. He is a high authority on medals, jetons, and tokens illustrative of the science of medicine. S. T. A.

Stork [O. Eng. *stork*: O. H. Germ. *storch* (> Mod. Germ. *storch*): Icel. *storker*. Cf. Gr. *τόρπος*, vulture]: any bird of the genus *Ciconia* and of the family *Ciconiidae*, which contains half a dozen species, all—save *Ciconia magnani*—inhabitants of the Old World. In general appearance they resemble the European stork (*Ciconia alba*). This is a large bird, about 3½ feet long; the head, neck, and body above, as well as below, are white, the wings partly black, and the bill and legs red. It is a migratory species, which in the warm season extends into Northern Europe, and in winter (as well as other seasons) is found in Northern Africa and Asia. It has no cry, but claps its bill together with a loud noise.

Storks are great favorites with the people, who conceive that their presence brings good luck. They often build upon the roofs of houses. They devour offal, reptiles, and other vermin. The stork displays remarkable affection for its young, and is of old a popular emblem of filial piety and conjugal faithfulness. See also *SHOEBILL* and *SHADOW-BIRD*.

Stork, CHARLES AUGUSTUS, D. D.: clergyman; b. at Jefferson, Md., Sept. 4, 1838; graduated at Williams College, Massachusetts, 1857; Professor of Greek Language and Literature, Newberry College, South Carolina, 1859-60; pastor Philadelphia, 1861-62, Baltimore, Md., 1862-81; Professor of Didactic Theology, Gettysburg, Pa., 1881-83. D. in Philadelphia, Dec. 17, 1883. After his death a selection from his writings was published, with the title *Light on the Pilgrim's Way* (Philadelphia, 1885), with a biographical sketch by his brother, T. B. Stork. See also *The Stork Family in the Lutheran Church* (Philadelphia, 1886).

H. E. JACOBS.

Storm: an intense atmospheric disturbance, which may be general or local, and may be characterized by high winds, when it is of especial importance to navigators, or by heavy precipitation of rain or snow, when it is most important inland, or by both wind and precipitation. General storms are areas of low pressure ("lows," or cyclones) of intense action, which travel eastward in temperate latitudes, but westward in the tropics. In summer very few of the "lows" are sufficiently intense to deserve the name of storm; in winter, perhaps, half of them are stormy, and in spring and autumn the ratio is still larger.

Stormy weather increases in frequency from the tropics toward the poles. The ocean in the vicinity of Cape Horn has the reputation of being the stormiest sea in the world, but the North Atlantic is the stormiest frequented ocean. The Pacific Ocean deserves its name only in lower latitudes. About the Aleutian islands and S. of Australasia it is very stormy. In the U. S. the storm frequency is greatest in New England and the region of the Great Lakes. Next come

the extreme northwest, and the Atlantic coast. The most destructive general storms in the U. S. are of tropical origin (see HURRICANES), but they affect only the eastern part of the country, and occur only in late summer and autumn. The general storms which enter the U. S. from the western Gulf coast or Mexico in the colder seasons bring warmer weather with abundant precipitation, sometimes torrential rains. Most of the general storms which affect the eastern part of the U. S. appear first in sight on the plains E. of the Rocky Mountains, in Alberta or Assiniboia. The general storms from the Pacific come from the N. W., and enter on the coast of British Columbia, Washington, and Oregon. General storms are unknown on the Pacific coast from Lower California to Panama, but are more common over the West Indies, and occasionally pass far enough westward to affect Spanish Honduras, Yucatan, and, to a less degree, British Honduras. The western portion of the Gulf of Mexico is subject to severe winter gales from the N. The American storms which last long enough to cross the Atlantic usually pass northward of the British islands. A few pass over Great Britain, or sometimes pass farther S., over France, or even Spain. The most of the European storms, however, do not previously appear on the American weather-map. Manchuria and Central and Northern Japan are crossed by many storms, and the Sea of Japan, on which Russia has established her Pacific ports, is very stormy. The typhoons of the China Sea bring stormy weather to the Chinese coast S. of Shanghai, to the Philippine islands, Formosa, and Southern Japan. Similar typhoons occur about the Samoan and Fiji islands and about the Mascarenes, and Southern New Zealand and Tasmania have stormy coasts. The general storms of South America enter from the Pacific on the coasts about Chiloe, then pass northeastward, affecting Patagonia, Southern Argentina, Uruguay, and the coasts of Southern Brazil.

The approach of a general storm is heralded by a falling barometer, a rising thermometer (generally), and a sheet of clouds ascending from the W. and preceded by long filmy streaks of cirrus. These signs usually give a day's notice, and the weather-map a notice of two or three days. The storm lasts from one to three days; the maximum of rainfall and wind usually precede by a few hours the minimum of air-pressure; and the retreat of the signs of the storm is more rapid than their advance with the approaching storm. The official forecasts of general storms can be made with more accuracy than those of moderate changes of weather, and their approach is heralded by storm-signals and warnings at the ports likely to be affected. (See WEATHER SIGNALS.) A general storm occupies an area of about 500 miles in diameter on the average, and may live from three days to a fortnight.

While the advance of the general storm can be forecasted with fair accuracy a day or two beforehand, the same is unfortunately not true of local storms. They are small, are not of long duration, travel but short distances, occur usually in warm weather, and only in the hottest part of the day. The individual storms give but brief warning of their approach, and though the conditions under which they develop are known and can be predicted, yet the individual storms will be only sparsely scattered over the area in which these conditions exist. Tornadoes and squalls are forms of local storms especially characterized by high winds, and thunder-storms and cloudbursts those characterized by heavy precipitation. In the U. S. local storms usually occur in the warm season a few hundred miles to the southward of a large, moist, and warm "low," especially when this is closely followed by a sharp fall of temperature. In the tropics they have no association with general areas of low pressure, but have a marked diurnal periodicity. For instance, at San José, Costa Rica, in the rainy season there is rain two days in three, and the rain is always after noon. Nine-tenths of the rain there falls between 2 P. M. and 7 P. M. See also SQUALLS, CLOUDBURST, METEOROLOGY, and OCEAN.

MARK W. HARRINGTON.

Storm, JOHAN FREDERIK: philologist; b. at Lom, Norway, Nov. 24, 1836; educated at the University of Christiania; Professor of Romanic and English Philology in the University of Christiania since 1873; author, among other works, of *Practical Course in English* (1862, in Norwegian); *The Romance Nations and Languages* (1871, in Norwegian); *Selections of Phrases for Tourists Traveling in Norway* (4th ed. 1881); *English Philology* (1879, in Norwegian); *Englische Philologie, die lebende Sprache* (revised translation

of preaching, 1881; 2d ed. 1902): *Det nyvordte Landmaal* (1888, concerning the attempt to create a new standard Norse on the basis of the Old Norse and the Norwegian dialects); *Romance Languages* (article in *Encycl. Britannica*, vol. xxi.); *French Dialogues, a Systematic Introduction to the Grammar and Idiom of Spoken French* (Norwegian ed. 1887; Danish, 1887, 1889; Swedish, 1887, 1891; German, 1888; Dutch, 1888, 1892; Finnish, 1892; English, 1892); also many articles in scientific journals.

R. I. W.

Storm, Tasmun, poet and novelist; b. at Husum, Schleswig, Sept. 14, 1817; studied jurisprudence at Kiel and Berlin; practiced law in his native city and later in Prussia; was appointed judge at Husum in 1874; retired from his position in 1880. D. July 4, 1888. In 1844 he published with Theodor and Trobo Mommensen his first collection of poetry, mostly lyric poems of exquisite simplicity and great depth of feeling. His great popularity he gained, however, by his *Tasmun Novellen* or short stories, of which he wrote a great many. The best known of them are: *Immerwies*, *Die Nannenschen*, *Ein gelbes Blatt*, *Ein stiller Meeresort*, *Viola leinbar*, *Die Nippengraber*, *Agnes schuermans*, and *Der Schwanenreiter*. His *Erinnerungen an Mörke* (1862) show how deeply he was influenced by the latter poet, whose fine lyric talent and graceful humor he frequently attained in his own writings. See Jacob Bächtold, *Mörke-Storm Briefwechsel* (1890); Fincher Wehl, *Theodor Storm* (1888).

JULIUS GÖPPEL.

Storm-area: an area on the weather-map over which the wind is high or the precipitation heavy, or both—a low of higher than average intensity. It can be at once distinguished by the crowding of the isobars and rain-symbols. The wind is the higher the closer the isobars are together. Heavy winds and torrential rains do not usually go together, though the former may follow the latter. The progress of a storm area is usually more uniform than that of gentler areas of low pressure. Western storm-areas usually increase in intensity as they pass eastward, but southern ones decrease in intensity and increase in size as they gain in height.

M. W. R.

Storm Lake: city, capital of Buena Vista co., Ia.; on Storm Lake, and the Ill. Cent. Railroad; 53 miles W. of Fort Dodge, 41 miles E. by N. of Sioux City (for location, see map of Iowa, ref. 9-14). It is in an agricultural and dairying region, and contains a national bank with capital of \$500,000, 2 State banks with combined capital of \$100,000, an incorporated bank, and 3 weekly newspapers. Pop. (1880) 1,934; (1890) 1,982.

Stormy Petrel, or Storm-petrel: See MORRIS GANNY'S CUCKERS.

Morris, RICHARD SALTER, D. D.: clergyman; b. at Longmeadow, Mass., Feb. 6, 1787; descended from a long line of ministers, his father, who bore the same name, having been thirty-three years pastor at Longmeadow; studied at Yale and at Williams, where he graduated in 1807; was licensed to preach by the Suffolk, Long Island, presbytery in 1809; preached at Islip and Smithtown, Long Island, 1809-49; spent a year at Andover Seminary, graduating in 1810; was ordained pastor of the First Congregational church at Braintree, Mass., July 11, 1811, and, with the exception of a period of five years spent as agent of the Home Mission Society, remained there until his death Aug. 11, 1873, after a pastorate of sixty-two years. He was the author of *The Boston Recorder* (1817-23) and senior associate editor of *The Congregationalist* (1850-55); contributed to *Pennsylvanian* and other periodicals; published a number of sermons.

Storrs, RICHARD SALTER, D. D., LL. D., L. H. D.: clergyman; son of Rev. Richard S. Storrs (1787-1870); b. at Braintree, Mass., Aug. 24, 1821; graduated at Amherst College 1839; studied law and afterwards theology at the Andover Seminary, where he graduated in 1845, and after serving for a year as pastor of a Congregational church in Haverhill, Mass., became in 1846 pastor of the Church of the Pilgrims, Brooklyn, N. Y., a position which he still occupies. The completion of the fortieth year of his pastorate was celebrated Nov. 18, 1886. Eminent as a preacher, he has also contributed much to current literature, and was from 1848 to 1901 one of the editors of *The Independent*, a religious weekly. He had a part in the *Report on the History and Recent Condition of the English Version of the Bible*, undertaken by the American Bible Society, and the *substantive and Doctrinal* in defense (1858); is the author of *The Graham Lectures on the Wisdom, Power, and Goodness*

of God, as manifested in the Constitution of the Human Soul (1859); a series of lectures on *The Conditions of Success in Preaching without Notes* (1870); *The Divine Origin of Christianity, substantiated by its Historical Effects* (1884); *Bernard of Clairvaux* (1892); besides numerous historical and literary, as well as religious, discourses. He became president of the American Board of Commissioners for Foreign Missions in 1867.

Revised by G. P. FURBER.

Story, JOSEPH, LL. D.: jurist; b. at Marblehead, Mass., Sept. 18, 1779; graduated at Harvard College in 1798; studied law, and in 1800 began practice in Salem; was a member of the State Legislature 1805-08, and the acknowledged leader on the Republican side, denouncing Jefferson's proclamation of embargo as the only measure, short of war, by which American commerce could be protected from the restrictions of the belligerent European powers. In 1809 he was elected a representative in Congress, where he urged a repeal of the Embargo Act, on the ground that it was a temporary measure, the purpose of which had now been attained. Having declined a re-election to Congress, he was in 1810 again chosen a member of the State Legislature, of which he was elected speaker. In 1811 he was appointed associate justice of the Supreme Court of the U. S.; in 1820 was a member of the convention for the revision of the State constitution. In 1829 he was chosen Dana Professor of Law in Harvard College, a position created for him, and which he held for the remainder of his life. D. at Cambridge, Mass., Sept. 10, 1845. In 1804 he published a volume of poems entitled *The Poems of Solitude* (most of the copies of which he bought up and destroyed), and in 1806 *Memorial of the Inhabitants of Salem*, a pamphlet addressed to President Jefferson relating to the infractions by foreign powers upon the neutral trade of the U. S. He also published many addresses, literary discourses, and reviews, etc., but his fame rests mainly upon his decisions, and especially upon his legal Commentaries, of which the following are the principal, all of which have passed through several editions, and most of which have been translated into German: *On the Law of Bailments* (1803); *On the Constitution of the United States* (1820); *On the Conflict of Laws, Foreign and Domestic* (1804); *On Equity Jurisprudence, as administered in England and America* (1843); *On Equity Pleadings* (1828); *On the Law of Agency* (1809); *On the Law of Partnership* (1841); *On the Law of Bills of Exchange* (1848); *On the Law of Promissory Notes* (1848). He also edited Chitty *On Bills of Exchange* and Abbott *On Shipping*, and left in MS. a *Digest of Laws*, supplementary to that of Coyns. As a constitutional lawyer he belonged to the school of Marshall, and supported the Federal authority. He was untiring in his work, and a great case lawyer. His commentaries and written decisions in his circuit comprise twenty-seven volumes, and his judgments in the Supreme Court an important part of thirty-four volumes more. A collection of his *Miscellaneous Writings* was published in 1832, and his *Life* has been written by his son, William W. Story (2 vols. 8vo, Boston, 1851).

Revised by P. SEYMOUR ALLEN.

Story, ROBERT HERBERT, D. D.: minister; b. at Rosneath, Dumbartonshire, Scotland, Jan. 28, 1835; educated at the Universities of Edinburgh, St. Andrews, and Heidelberg; assistant minister at St. Andrew's, Montreal, Canada, 1859-60; in Rosneath, as his father's successor, 1860-87; since 1887 Professor of Church History in the University of Glasgow, second clerk of the General Assembly of the Church of Scotland, and chaplain to the Queen; editor of *The Scottish Church* (a monthly magazine) since its foundation in 1886; the first lecturer on the Lee foundation, St. Giles, Edinburgh, 1896. Besides many contributions to various periodicals Dr. Story has published *Robert Hervey of Rosneath, a Memoir* (London, 1862); *Christ the Comforter, or Scriptures, Hymns, and Prayers for Times of Trouble and Sorrow, selected and arranged* (Edinburgh, 1865); *Life and Remains of Robert Lee, D. D.* (London, 1870); *William Caxton* (1874); *Creed and Confessors: Sermons* (1878); *Health Haunts in the River Nile* (Dulley, 1881); and *Nugae Ecclesiasticae* (Edinburgh, 1884). C. K. DUFF.

Story, WILLIAM WETMORE: sculptor; son of Joseph Story, LL. D.; b. at Salem, Mass., Feb. 19, 1819; studied law; was admitted to the bar, and published several legal books—*Report of Cases* (1842-47); *Treatise on the Law of Contracts* (1844); *The Law of Sale of Personal Property* (1847); edited the *Life and Letters of Joseph Story* (1851). About 1848 he abandoned law for sculpture, and since that time

he has resided chiefly in Rome. Besides the practice of his art he has been a somewhat prolific writer. He published *The American Question* (1862); *Roba di Roma* (1862); *Proportions of the Human Figure* (1866); *Graffiti d'Italia* (1869); *A Roman Lawyer in Jerusalem* (1870); *The Castle S. Angelo and the Evil Eye*, being a second volume of *Roba di Roma*, in 1877; and five volumes of poems. As a sculptor he is known chiefly by his large allegorical statues, *Medea*, *Cleopatra*, *The African Sibyl*; by the statue of George Peabody executed for the corporation of London; the statue of Edward Everett in the Boston Public Garden; the monument at San Francisco of Francis Scott Key; and busts of his father, James Russell Lowell, William Cullen Bryant, Josiah Quincy, and Theodore Parker. He was made Chevalier of the Legion of Honor at the Paris Exposition of 1878.

Stothard, CHARLES ALFRED: painter and architectural draughtsman; son of Thomas Stothard, painter; b. in London in 1786; early distinguished himself by his skill as an artist. His best-known painting, *The Death of Richard II.*, was exhibited in 1810, and in the following year he began the publication of the *Monumental Effigies of Great Britain*, a series of etchings with descriptions, completed (1811-23) after his death by others, and valuable for its accuracy. He was selected by the Antiquarian Society to make drawings of the famous Bayeux tapestry, and in 1819 made sketches from the newly discovered old pictures on the walls of the Painted Chamber of the House of Lords. D. at Bere Friars, in Devonshire, England, May 27, 1821.—His widow, ANNE ELIZA (d. 1883), who assisted her brother, Mr. Kempe, in the completion of the *Monumental Effigies*, afterward married the Rev. Edward Bray. She was the author of several creditable novels and other works written during her second marriage.

Revised by RUSSELL STURGIS.

Stothard, THOMAS, R. A.: painter and designer; b. in London, Aug. 17, 1755; was apprenticed to a designer of patterns for the silk trade, but soon became an illustrator of books, and finally a painter. He illustrated the set of *The Novelists' Library*, begun about 1780, and other popular works, and became known as a most prompt and useful workman, so that he was constantly employed. He was elected fellow of the Royal Academy in 1794, and its librarian in 1812. His illustrations for books number more than 4,000, among them being those for *Robinson Crusoe* and *The Pilgrim's Progress*, 1788, the *Rape of the Lock*, 1798, the works of the German poet Gessner, 1802, Cowper's *Poems*, 1825, and Rogers's *Italy and Poems*, of which he illustrated not only the splendid octavos of 1830 and 1834, but also the small 12mo editions with wood-cuts. His work as an illustrator of books is graceful and pure, not very realistic nor careful about costume and architecture or other matters where historical accuracy is thought necessary, but artistic in a very high degree. Among his best paintings are the *Canterbury Pilgrims*, the *Flitch of Bacon*, and *Four Periods in a Sailor's Life*. Besides his work in pure art he made many designs for goldsmiths and other decorative workers. D. in London, Apr. 27, 1834. See the *Life* by Mrs. Bray (1851).

Stoughton, stō'tūn: town; Norfolk co., Mass.; on the N. Y., N. H. and Hart. Railroad; 17 miles S. of Boston (for location, see map of Massachusetts, ref. 5-1). It contains the villages of Stoughton, North Stoughton, and West Stoughton; is principally engaged in the manufacture of boots, shoes, and rubber and woolen goods; and has 4 hotels, a public high school, 17 district schools, public library (founded in 1874), a co-operative bank, and 2 weekly newspapers. The assessed valuation in 1894 was \$2,819,252. Pop. (1880) 4,875; (1890) 4,852.

Stoughton: city (founded in 1847); Dane co., Wis.; on the Yahara river, and the Chi., Mil. and St. Paul Railway; 14 miles S. S. E. of Madison, the State capital (for location, see map of Wisconsin, ref. 7-D). It is in the center of the great tobacco belt; and contains 8 churches, high school, academy, 4 public-school buildings, water-works, electric lights, manufactories of carriages and wagons, cigars, harness, and flour and feed mills, 2 State banks with combined capital of \$55,000, and 3 weekly newspapers. The city is an important tobacco-market. Pop. (1880) 1,353; (1890) 2,470; (1895) estimated, 3,000.

EDITOR OF "COURIER."

Stoughton, JOHN, D. D.: clergyman and author; b. at Norwich, England, Nov. 15, 1807; educated at Highbury College, Islington, and University College, London; pastor

of Congregational churches at Windsor 1832-43, at Kensington, London, 1843-75; Professor of Historical Theology and Homiletics in New College, St. John's Wood, London, 1872-84. He was Congregational lecturer 1855, and chairman of the Congregational Union 1856. He edited for many years *The Evangelical Magazine*, and published many very popular as well as scholarly volumes, including *Lectures on Tractarian Theology* (London, 1843); *Windsor: a History and Description of the Castle and the Town* (1862); *Homes and Haunts of Luther* (1875); *Italian Reformers* (1881); *Spanish Reformers* (1883); but chiefly the series of Church histories of England from the opening of the Long Parliament (1640) to 1800, issued in revised form in 1881 under the title *History of Religion in England* (6 vols.); supplement carrying the story to 1850, 1884, 2 vols. He issued his autobiography, *Recollection of a Long Life*, in 1894.

Revised by G. P. FISHER.

Stourbridge, stér'brij: town; in Worcestershire, England; on the Stour, 12 miles W. by S. of Birmingham (see map of England, ref. 9-G). It manufactures iron, glass, earthenware, and fire-bricks, the latter from a peculiar kind of clay called Stourbridge clay, on which fire has only a small effect. Pop. (1890) 9,866.

Stout: See BEER.

Stove [from Dutch *stoof*, foot-stove, drying-room; Germ. *stube* < O. H. Germ. *stuba*, room that can be heated; bath-room. The original meaning was "heated room." How the Romanic words: Fr. *étuve*, Ital. *stufa*, Span. *estufa*, cf. Fr. *étouffeur* are related is still a question]: an apparatus for retaining and diffusing heat, as for warming and ventilating or cooking. In the Middle Ages stoves, constructed of brick or tiles and sometimes of slate or steatite, were used for warming dwellings. They were large, often filling the side of a room, and in Scandinavia their broad flat surfaces were sleeping-places. The fire was kindled at the bottom, and the heat and smoke passed through flues before making their exit into the chimney. Some of these stoves had ovens and flues for cooking, and when once thoroughly heated required fuel but once in twenty-four hours. An early attempt at making a stove or closed fireplace of iron was made by Cardinal Polignac in France. He published a description of this in *La Mécanique du Feu, ou l'Art d'en augmenter les Effets, et d'en diminuer la Dépense* (1709). The Polignac fireplaces were constructed with hollow backs, hearths, and jambs of iron to economize the heat. Des Aguliers translated Polignac's treatise (London, 1716), and modified his fireplaces so as to use them for coal. Neither these nor the Holland stoves, which were introduced soon after (plain box stoves with a small smoke-pipe or flue at the top, and a single door into which the wood or coal was thrown), became popular in England, owing to the prejudice of the people in favor of open fires. Dr. Franklin, writing of stoves after his invention in 1745, refers to a German stove recently introduced into England, consisting of an iron box made of five plates fastened together with screws, one side of which was left open, but when the stove was set, this open side, with the smoke-pipe, was in an ante-room, while the body of the stove projected through the partition to warm a larger room, the fire being fed and the smoke conducted off in the ante-room. Franklin's stove was a great advance. Although, in its ordinary use, a fireplace, it was capable of being closed, and had a downward draught, distributing the heat through the air-boxes in its sides, till at last the remainder of the heat escaped with the smoke through a flue leading into the base of the chimney. A register or "damper" of sheet-iron was introduced into the descending flue, which checked and controlled the fire. In 1771, and later, Franklin invented other stoves—one for burning bituminous coal which would consume its own smoke and had a downward draught, and another intended for the same purpose, having a basket grate or cage, with movable bars at the top and bottom, supported by pivots at its center. The latter, after being filled and kindled at the top, could be inverted and so made to burn from the base. Between 1785 and 1795 Benjamin Thompson, Count Rumford, devised several improvements in stoves, intended to economize fuel and heat.

In the U. S. before 1825 the use of stoves, generally of the box pattern and very rude, was confined to shops and offices, public rooms, and churches in cities and larger villages. In the country the churches were seldom warmed, but the women carried foot-stoves, and the men protected their feet by stout overshoes called "boxes." Among the wealthy in cities canal and other English coal ("sea coal") was burned

in improved grates or in the Remond stove lined with fire-brick. A greater number in cities and larger villages used the Franklin stove, burning wood and making an open fireplace of it. The rest of the world used the old open open-hearth fireplaces, burning wood logs. A large brick oven adjoined the kitchen fireplace, and required a large quantity of wood to heat it. Until 1825 stoves in the U. S. were made almost exclusively at blast furnaces and directly from the ore, instead of being made in foundries by cupola furnaces from pig iron, as they were later, and they were consequently much heavier and ruder than now and had loose and imperfect joints. Most of them were made in New Jersey, Pennsylvania, and Ohio, though a few were cast quite early in the furnaces at Cold Spring and Warwick, N. Y., and at Salisbury and Casson, Conn., and from 1850 to 1855 considerable stove-making was done in Rutland co., Vt. From 1795 to 1825 no material progress was made in the construction of stoves. Those for heating purposes were either box stoves made on the old German plan, an oven being sometimes added, placed directly over the fire, or portable and partly open fireplaces made on Franklin's plan. For cooking purposes Remond's cooking-stoves or ranges fitted with fire-top or scapstone, and with a ventilating oven, which had been introduced in New York as early as 1798 and into Boston about 1800, were gradually coming into use. After the opening of the Erie and Champlain Canals, the introduction of steamboats on rivers, and the first beginnings in railway travel, the facilities for transportation for heavy goods were so increased that the manufacture of stoves, and especially of cooking-stoves, became an important industry. As yet these were universally wood stoves, but the anthracite coal was destined to create a revolution in stoves. Jordan L. Mott and James Wilson, both of New York, made self-feeding stoves between 1827 and 1831 that would burn the British coals, and were an improvement on previous inventions, but it was not until 1832, when Mr. Mott had demonstrated that an anthracite fire could be made successfully from nut and pine-wood coals, and that the depth of the column of mud in his self-feeders must be in direct proportion to its size, the largest coal requiring the highest column, that anthracite coal stoves became salable. Early in 1833 he built a small cupola furnace and cast his stove-plates from pig iron of the best quality, fluting them to prevent their cracking. This was among the first attempts to make stove-plates from pig iron and to make the plates light, even, and smooth. The first cooking-stoves made in Albany (1835) were of the old template oval pattern, with oven above the fire and a single hole in the top. These were followed by the saddle-bag pattern, having the oven in the middle over the fire and the stove-collar and pipe over it, while on either side was an oval projection with a boiler-hole on a level with the stove-top, these projections resembling very closely an inverted pair of saddle-bags. The next pattern was the horse-block, so called from the rear portion of the stove, which contained the oven, being a step higher than the front. The entire stove, having a movable top revolved by means of a crank, so as to bring any desired vessel directly over the fire, was a later invention. Then came the bush stove, both for wood and coal, having the fire above the oven and reversible flue which carried the heat and flame around, behind, and below the oven before reaching the smoke-pipe, which was merely on a plane with the avendour. There have been hundreds of modifications of this pattern, but in all of them the reversible flue has been the predominating feature. In heating-stoves there has been a great variety of forms and some new principles have been introduced, though many of these seem to have been anticipated by the inventions of Dr. Neil Arnott. The problem of adapting the heating stove to the use of anthracite coal and utilizing its great heat-producing power economically was solved by President West, of Union College, who spent years and much money in perfecting his stove. The self-feeder had previously been made both in England and in France, but one of its applications was a device of Dr. West, which he applied to several stoves, and others were not slow to follow. Samuel Paxon, of Troy, and Anson Atwood, of Brooklyn, introduced the hot-air current to facilitate combustion and radiation of heat, or at least are believed to have improved upon that idea.

In cooking-stoves and fixed and portable ranges the number of inventors and manufacturers is large. One of the most ingenious inventors of cooking-stoves was P. V. Stewart, of Troy, N. Y., whose stoves were, and with some modifications still are, very popular. Dr. Nuttall invented several

excellent cooking-stoves. Wilson, Troy, New York; Buffum, Philadelphia; Furstung, Cleveland; Leonard, Chicago; Quincy, St. Louis; Milwaukee, Boston; Frothingham, Woburn, and Detroit have each a number of manufacturing establishments in the production of stoves, ranges, and heaters. The efforts of the stove-makers since 1800 have been directed rather toward completing the adaptation of the principles of heat-burning, hot-air heating, and the anti-splinker arrangement in stoves, and greater security and perfection of the castings than to the discovery of any new principle. Portable and brick-set ranges in great variety are now produced, with similar arrangements for heating water as in the cooking-stoves. They are well constructed, have all the improved facilities for labor and fuel saving, and are particularly noteworthy for the perfection of their castings and finish. A few manufacturers make stoves entirely of sheet-iron or enameled. Such stoves retain the heat for a long time and require but a small amount of fuel, which they consume entirely.

While the use in the U. S. of cast iron has continued for heating-stoves and the majority of cooking-stoves, there has been a growing application of steel to the construction of cooking-ranges. Since 1865 an important development has been in the use of gasoline as a fuel—a process that began in the West and has extended eastward. At first such stoves were made so as to burn the gasoline direct, but in the new forms called pressure stoves the gasoline is first changed into gas. Kerosene has also been used as a fuel. The employment of illuminating gas as a fuel is steadily growing, and utilities improved burners and cheapened gas have led to the introduction of many forms of gas stoves for use in apartments. In Great Britain slot meters are employed by means of which a given amount of gas for a penny is turned on and automatically turned off when the amount has been consumed. The use of electricity as a heat-producer is recognized, and forms of heating apparatus for it were shown at the World's Columbian Exposition held in Chicago in 1893, but as yet its employment is slight. All the stoves used in the U. S. are of domestic manufacture. The National Association of Stove-manufacturers reported in May, 1904, that there were 274 firms engaged in that business in 1903, whose sales during that year amounted to \$40,035,700. There is an export trade of gas and gasoline stoves to South America, Mexico, etc., and a slight exportation of anthracite stoves to Europe.

Stow, BARRY, D. D.: clergyman and author; b. at Crofton, N. H., June 16, 1801; graduated at Columbian College, District of Columbia, in 1825; edited *The Columbian Star* 1825-27; became pastor of the Baptist church at Portsmouth, N. H., in 1827, of the Babylon Place church, Boston, in 1832, and of the Howe Street (now Cleveland Avenue) church in 1845. He was prominent in the missionary enterprises of the denomination, and president of the trustees of Newton Theological Seminary. Besides numerous contributions to religious periodicals, he published *History of Harriet Beecher* (1832); *Hebrew's Pilgrimage* (1835); *History of the English Baptist Mission to India* (1835); *The Danish Mission on the Coast of Greenland* (1837); *Question-bank of Christian Doctrine* (1848); *Christian Brotherhood* (1850); *First Things* (1850); and, in conjunction with Rev. Samuel P. Smith, *The Psalter*, a collection of hymns largely used by Baptists (1849). D. in Boston, Dec. 27, 1860. See *Life*, by R. H. Nye (1870). Revised by W. H. WHEAT.

Stowe, CALVIN ELLIS, D. D.: clergyman, educator, and author; b. at Natick, Mass., Apr. 6, 1807; graduated at Bowdoin College in 1824, and in 1829 at Andover Theological Seminary; was Assistant Professor of Sacred Literature at Andover, and assistant editor of *The Boston Herald* 1828-30; Professor of Languages in Dartmouth College 1830-33, of Biblical Literature in Lane Seminary, Walnut Hill, near Cincinnati, 1833-36, and of Natural and Revealed Religion in Bowdoin College 1836-52. In 1852 he became Professor of Sacred Literature in Andover Seminary, but resigned in 1864 and removed to Hartford, Conn. In 1856 he married Harriet Elizabeth Beecher. In the same year he was sent by the State of Ohio to examine the public-school systems of Germany. Upon his return he published a report on *Elementary Education in Europe*, which was distributed at the public expense to every school district in Ohio and was also adopted by the Legislatures of several other States. He translated from the German Jakob's *History of the Hebrew Commonwealth* (Andover, 1858; 2 vols., London, 1859); prepared from the *Protestantism of Jacobus*

volume of *Lectures on the Sacred Poetry of the Hebrews* (1829); began an *Introduction to the Criticism and Interpretation of the Bible*, of which only vol. i. was published (Cincinnati, 1835); and the *Origin and History of the Books of the Bible* (part i., containing the New Testament, Hartford, 1867). He also published several addresses and educational reports, and contributed largely to religious periodicals. D. at Hartford, Conn., Aug. 22, 1886.

Stowe, HARRIET ELIZABETH (Beecher): author; daughter of Lyman Beecher; b. at Litchfield, Conn., June 14, 1811. At the age of thirteen she was sent to the school kept by her sister Catherine at Hartford, where she studied and taught until 1832, when she removed with her father to Cincinnati; was married in 1836 to Rev. Calvin E. Stowe, then professor at Lane Seminary, Cincinnati. In 1849 she published *The Mayflower, or Sketches of the Descendants of the Pilgrims*, and in 1851 began in *The National Era* of Washington a serial story designed to illustrate the horrors of African slavery, which was published separately in 1852 under the title *Uncle Tom's Cabin*, and attained a rapid and almost unparalleled success at home and abroad. Within five years 500,000 copies were sold in the U. S.; within ten years there had been made from it two or three French versions and more than a dozen German ones. It was also translated into Danish, Swedish, Portuguese, Spanish, Italian, Welsh, Russian, Polish, Hungarian, Wendish, Wallachian, Armenian, Arabic, Rumanian, Chinese, and Japanese. It did more than any other literary agency to rouse the public conscience against slavery, and has been repeatedly dramatized. In 1853 she put forth a *Key to Uncle Tom's Cabin*, in which were set forth the main facts upon which the story was based, together with many incidents in corroboration of its truthfulness. In 1850 Mrs. Stowe removed to Brunswick, Me., where her husband had been appointed to a professorship in Bowdoin College. In 1852 they went to Andover, Mass., where he had accepted a chair in the theological seminary. In 1853 she accompanied her husband and her brother to Europe, and upon her return published *Sunny Memories of Foreign Lands* (2 vols., 1854). Her subsequent writings, which were mostly inferior, usually first appeared in periodicals, especially in *The Atlantic Monthly* and in the *Hearth and Home*, of which she was for a time one of the editors. Among these, as published separately, are *Dred*, a tale of the Great Dismal Swamp, subsequently published under the title *Nina Gordon* (1859); *The Minister's Wooing* (1859); *The Pearl of Orr's Island* (1862); *Agnes of Sorrento* (1863); *Oldtown Folks* (1869); *Pink and White* (1871); *My Wife and I* (1872); *Bible Heroines* (1878); *Paganic People* (1878); *A Dog's Mission* (1881); and a volume of religious poems. Her paper in *The Atlantic Monthly* in 1869, *The True Story of Lord Byron's Life*, started an unfortunate scandal, and she replied to her critics with *Lady Byron Vindicated, a History of the Byron Controversy* (1869). In 1864 Mrs. Stowe removed to Hartford, Conn., where she still (1895) resides. See the *Life* by her son (Boston and New York, 1889). HENRY A. BEERS.

Strabismus: See SQUINTING.

Strabo: Greek geographer; b. at Amaseia, in Pontus, 63 B. C.; d. in the reign of Tiberius after 21 A. D. He received an excellent education under eminent masters in philosophy and in literature, went to Rome about 29 B. C., and undertook extensive travels in Asia Minor, Egypt, Greece, and Italy. At a mature age he wrote a history, which is lost, and a geography in seventeen books, which has come down to us, and is especially valuable for its historical notes, which are the more abundant as Strabo looks at geography from an historical point of view, and shows that he is a disciple of Polybius. His work is unequal, and it is a natural inference that where his descriptions are meager and incorrect his information is derived from books, and that where they are full and accurate we have before us the result of personal observation. His style is simple, and the grouping of the heterogeneous materials shows something of the Greek feeling for proportion. The first two books of his works form an introductory to geography; with the third the description begins. Eight books are devoted to Europe, six to Asia, and the seventeenth and last to Egypt and Libya. Editions by Kramer (3 vols., 1844-52) and Meineke (3 vols., 1852-53). English translation by Falconer and Hamilton (3 vols., 1854-57). The French translation, made by La Porte du Theil, Coray, and Gosselin, at the command of Napoleon I. (5 vols., 1805-19), is very rich in notes. There is a valuable German translation, with notes,

by Groskurd, 1831-34. On Strabo, see Dunbury, *History of Ancient Geography*, vol. ii., 209, seq.; and also the introduction to Tozer's *Selections from Strabo* (1893).

Revised by B. L. GILDERSLEEVE.

Strabo, WALAHRID (Walafridus Strabus, "the Squint-eyed"): ecclesiastic and author; b. in Suabia about 809; educated in the Benedictine abbey school of Reichenau, on the island in Lake Constance; then at Fulda, 54 miles S. E. of Cassel, under Rabanus Maurus (826-829). From Fulda he went to Aix-la-Chapelle and became tutor to Charles, son of the Emperor Louis the Pious. The latter made him abbot of Reichenau 838. He was driven from his post by Louis the German 840, but restored 842. He died while crossing the Loire, Aug. 18, 849. He was a very prolific writer. His principal work, the so-called *Glossa ordinaria*, is a huge exegetical compilation, the oldest printed edition of which—without date and place, but about 1480—comprises four volumes in folio. It was for several centuries the principal source and the highest authority of biblical science in the Latin Church, being in use, indeed, to the seventeenth century. His *De exordiis et incrementis rerum ecclesiasticarum*, printed in Hittorp's *De officiis divinis* (Cologne, 1668), and in several later editions, best by A. Knoepfler (Munich, 1890), is an interesting handbook in ecclesiastical archaeology. To him we owe the authentic lives of St. Gall (ed. R. Shute, St. Gall, 1890) and St. Othmar. He was a poet and not a mere monastic rhymester. The most curious of his poems is his *Vision of Wettin*, which relates his journey to hell, purgatory, and paradise. He has the hardihood to introduce Charlemagne in purgatory suffering for his incontinence. Another poem, and perhaps his best, is *Hortulus*, upon the plants in the convent garden. See his works in Migne, *Pat. Lat.*, cxlii, cxiv., and his poems separately in Dümmler, *Poet. Lat. ævi Carolini II.*, 259-473. SAMUEL MACAULEY JACKSON.

Strachey, WILLIAM: historian; b. in England about 1585; was the first secretary to the colony of Virginia 1610-12, having been shipwrecked on the Bermudas 1609 with Gates, Somers, and Newport; wrote *A True Reportory of the Wracke and Redemption of Sir Thomas Gates, upon and from the Islands of the Bermudas, in Purchas's Pilgrims* (vol. iv., lib. ix., cap. vi.), upon which Shakespeare appears to have drawn in his description of a storm in the *Tempest*—an inference strengthened by the reference in the same drama to the "still-vexed Bermoothes"; compiled *For the Colony in Virginia Britannia, Leaves Divine, Moral, and Martiall* (London, 4to, 1612); and was author of *Historie of Travaile into Virginia Britannia*, written as early as 1618, and first published by the Hakluyt Society from an original MS. (No. 6, 1849) under the editorship of Richard H. Major—a quaint and valuable work which supplies the means of correcting the false details of the early history of Jamestown (especially in relation to Pocahontas) which have been so often repeated upon the authority of Capt. John Smith. Strachey projected a larger work, of which this volume forms but "the first and second books of the first decade." The time and place of his death are unknown. See *A History of American Literature*, by Moses Coit Tyler (1878), vol. i., pp. 41-45. Revised by H. A. BEERS.

Stradivarius, ANTONIO: maker of musical instruments; b. at Cremona, Italy, in 1644; learned the art of making violins and other string instruments from Nicolo Amati, under whom he worked for several years; in 1668 began to make violins marked with his own signature, and by degrees not only rivaled but even outshone his master. His best instruments were made in the period between 1700 and 1725, and command from \$1,000 to \$3,000. D. Dec. 17, 1737.

Strafford, THOMAS WENTWORTH, Earl of: minister of Charles I.; b. in London, Apr. 13, 1598; studied at Cambridge; traveled on the Continent; sat in Parliament, and was at first active in opposition to the court, though unwilling to go to radical lengths, and had no sympathy with the religious policy of the Parliament. In 1628 he went over to the king's side; was created Baron Wentworth, then viscount, lord president of the council of the North, a privy councillor in 1629, and lord deputy of Ireland in 1633. His rule in Ireland was harsh and despotic, aiming at the establishment of his system of "thorough" or the absolute power of the king, and he acquired the designation of "the wicked earl." In Jan., 1640, he was created Earl of Strafford, and soon afterward prepared an army in Ireland to aid against the Scots. Upon his return to England he supported the harshest measures of the crown. The famous Long Parliament convened Nov. 3, 1640, and within eight

John Pym appeared before the bar of the House of Lords and in the name of the House of Commons impeached him of an attempt to overthrow the public liberties and subvert the public rights. He defended himself personally and with such success that the Commons abandoned their original impeachment and passed a bill of attainder. The Peers were later overruled by the fierce attitude of the Commons and dared not refuse their assent to the bill, which was sent to Charles for his sanction. The king wished to save his minister, for whose safety he had pledged himself, but fearing a violent revolution he reluctantly gave his assent, and Strafford was brought to the block on Tower Hill, May 12, 1641. That he had been proved guilty of no crime which by the strict letter of the law was a capital one is certain, and the bill of attainder was in fact a retrospective law, justifiable only on grounds sufficient to warrant any other revolutionary proceeding. The act of attainder was reversed in 1692 after the restoration of Charles II., and the estates of Strafford were restored to his son. His *Letters and Dispatches*, edited by Dr. Kewley, were printed in 1730; his *Life* has been written by Elizabeth Cooper (1874) and by H. D. Traill (1899). The circumstances of his life have occasioned much controversy. Mansel's account counts him most severely, while Gardiner takes a more favorable view of his political career.

Revised by F. M. Carey.

Straight University, a coeducational institution at New Orleans, La.; founded by Seymour Straight and incorporated in 1903. It is for Negroes exclusively, and is under the care of the American Missionary Association. It has classical, normal, manual-training, theological, and four other departments; a faculty numbering 93, and 600 students.

Strain: the force applied to a rope or bar, or the amount of change of shape produced by the force; the word being generally used by practical engineers in the first sense and by scientific writers in the second. See **STRESS**.

Straits: See **PHYSIOGRAPHY**.

Straits Settlements: a British crown colony in the East Indies, including Malacca, Penang or Prince of Wales Island, with the provinces of Wellesley on the continent, and Singapore. The Settlements were made a separate dependency of the British crown in 1824, and placed under the Governor-General of India. On Feb. 1, 1897, the connection with India ceased, the province became a crown colony, and is administered by a governor residing at Singapore. In 1897 the Cochin or Keling Islands were attached to the colony, and in 1899 Christmas Island. The British possessions of 1,472 sq. miles were inhabited (1891) by 518,042 persons, of whom 213,078 were Malays, 227,922 Chinese, and 56,327 natives of India. The protected Malay states of the peninsula (Perak, Selangor, Johor, Sungai Ujong, Negri Sembilan, and Pahang) comprise about 34,000 sq. miles. Pop. (1891) 418,567, not including Johor, which has an estimated population of 300,000. The internal administration of these states is in the hands of the British residents. Mining is actively carried on, and large supplies of tin are exported from Perak and Selangor. Fifteen hundred British troops and a few vessels are sufficient in time of peace to maintain order and punish piracy.

Revised by M. W. HARRINGTON.

Stralsund, *strahl'sunt*: town; in the province of Pomerania, Prussia; on the narrow strait which separates the island of Rügen from the mainland; has a good harbor and is strongly fortified (see map of German Empire, ref. 2-5). It is an old town (founded in 1209), and played a conspicuous part—first as a member of the Hanseatic League, then during the Thirty Years' war as a fortress. It has manufactures of paper, tobacco, oil, spirits, and mirrors, and an extensive export trade in grain, wool, cattle, and horses. Pop. (1890) 27,814.

Revised by M. W. HARRINGTON.

Stramonium [Mod. Lat., the thorn-apple, also the drug contained in its seeds and leaves]: a drug consisting of the seeds and leaves of *Datura stramonium*, an annual plant of the family *Solanaceae*, growing rankly as a weed throughout almost all the temperate and warm countries of the world. The herb, called thorn-apple, and in the U. S. also James' weed, is a leafy plant, found mostly in rank soil near dwellings. Its average height is about 3 feet. It has an erect stem, with many branches beset with large triangular leaves, irregularly sinuate and dentate. The flower is large, white, salubrious; the fruit a large, fleshy, four-lobed capsule, thickly covered with sharp spines. The seeds are flat and of a dark-brown color. Both leaves and seeds contain an alkaloid, *atropine*, closely analogous both in chemical prop-

erties and poisonous character to *atropine*, the alkaloid of belladonna. Medicinally, stramonium is a duplicate of belladonna, and is used for similar purposes. One of its most frequent employments is for the relief of asthmatic attacks, for which purpose the dried leaves or powdered roots are smoked. Stramonium is a powerful poison, the effects being identical with those of belladonna.

Revised by H. A. HARR.

Strandberg, KARL VILHELM ARVID (Tells Quilist); poet; b. in Mölnderslund, Sweden, Jan. 16, 1870. While a student at the University of Lund he wrote a number of songs, chiefly under the influence of the German political poetry of the period. From this he later freed himself entirely. His principal collection of poems is *Sångens Skugga* (Shadow in Armon), which shows with patriotic fire. He was the author of a number of occasional poems and translated Byron and Möller. D. in Stockholm, Feb. 5, 1877. *Arvids Vitterhets Arkivet* (3 vols., Stockholm, 1877-78).

H. K. DENNIS.

Strang, Sir (Robert), engraver; b. on Pomona, one of the Orkney Islands, July 14, 1721; studied painting, but in 1740, having joined the army of the Pretender, was obliged to conceal himself; afterward went to Paris, where he became a pupil of Le Bas, the famous engraver, and in 1751 established himself in London as an historical engraver, in which department of art he acquired great eminence. He was knighted in 1767. He published *A Descriptive Catalogue of Pictures, etc., collected and drawn by Sir Robert Strang* (1769) and *An Inquiry into the Rise and Establishment of the Royal Academy of Arts* (1775; new ed. 1820). A collection of 817 of his principal engravings has been issued in a magnificent atlas, and his *Memories*, by James Dennistoun, appeared in 1855. D. in London, July 5, 1782.

Revised by ROBERT STRONG.

Strangles: in the horse, an abscess which occurs between the branches of the lower jaw. If possible, the animal should be induced to eat. The throat should be thoroughly fomented, and as soon as the sore comes to a head it should be opened, whereupon recovery will generally follow. Sometimes, however, the lymphatic glands appear to be inflamed, and occasionally metastatic abscess appears in distant parts of the body. This disease is considered contagious, and there is a similar infectious disease, also called strangles, among swine.

Strangulation [from Lat. *strangulatio*, deriv. of *strangula* (whence Eng. *strangle*), from Gr. *strangulatio*, strangle, deriv. of *strangulatio*, strangle, deriv. of *strangulatio*, to strangle; primarily, the mechanical closure of the air-passages of the neck, so as to prevent respiration. Death by strangulation is speedy, but there may be a chance of recovery for a considerable period. Artificial respiration, stimulant applications to the extremities and chest, and of ammonia to the nostrils, should be tried. When other means have failed the galvanic battery may be employed. After apparent recovery, death may speedily occur from secondary causes.

Revised by W. PRETTE.

Strangury [from Lat. *stranguria* = Gr. *stranguria*; *stranguria*, *stranguria*, drops + *stranguria*, urine water]: a suppression of the urine. The name is especially applied to such suppression when it depends on the presence of spasm or tension of the urethra. It may be caused by the too free use of Spanish-fly blisters or of oil of turpentine, or it may attend the presence of calculi in the bladder. The warm bath, hot fomentations, mucilaginous drinks, bland enemata, and the like will usually relieve the untoward symptom.

Strassburg, Germ. *strass'burgh* (anc. *Argentoratum*; Fr. *Strasbourg*): important fortified town of Alsace, on the Rh. the French and the Rhine-Rhône and Rhine-Meuse Canals; 2 miles W. of the Rhine; junction of the railways of Southern Germany and France (see map of German Empire, ref. 5-11). It is ill built, with narrow streets and high houses, but is improving. The most remarkable of its public buildings is the cathedral, with a tower 466 feet high, founded in 510 by Chlodwig, but the older structure was destroyed by lightning in 1097. In 1015 Bishop Werner of Habsburg laid a new foundation, and in 1273 the main building was finished. The tower was begun in 1277 by Erwin von Steinbach, and completed in 1439 by J. Hölle, of Colmar. In this building is the famous clock made (147-80), representing our planetary system and its constellations. The Church of St. Thomas, founded in 1041, and containing a monument of Marshal Saxe, and the New

Church are also noticeable. A German university was opened May 1, 1872, and numerous educational and benevolent institutions exist. Commerce and industry flourish in consequence of the favorable situation on the river. Important tobacco-factories are in operation, numerous breweries, printing establishments, oil and saw mills, wool-spinning establishments, manufactures of oilcloth, straw hats, gloves, paper-hangings, chocolate, mustard, goose-liver pies, soap, candles, chemicals, musical instruments, furniture, jewelry, etc. The cultivation of vegetables, fruits, and flowers is considerable. Under French dominion the city had a strong bastioned circumvallation, but since it has become part of the German empire a new system of fortification has been applied, consisting of a number of large, strong forts surrounding the inner fortifications, so that an army can encamp between the city and the forts, while the city is entirely protected from the enemy's fire by the outer forts.

During the Middle Ages Strassburg was one of the most powerful free cities of the German empire, and during the period of the Reformation it played a prominent part as one of the centers of the Protestant movement. Sept. 30, 1681, Louis XIV. captured it, and by the Peace of Ryswick he retained it. It continued, however, a completely German city down to the time of the Revolution, when French gradually gained the ascendancy. By the Peace of Frankfurt (1871) it returned to Germany, and is the seat of the civil and military government of Alsace-Lorraine. Pop. (1890) 123,500. Revised by M. W. HARRINGTON.

Strategy [from Gr. *στρατηγία*, office of a general, deriv. of *στρατηγός*, general; *στρατός*, army + *ἄγω*, lead]: that branch of the art of war which has for its object the initiation and conduct of wars, campaigns, and battles in such a manner as (1) to take advantage of all available means for securing success, and (2) to cause the greatest benefits to result from victory and the least injury from defeat. The scope of strategy was formerly considered as restricted to the movements of organized armies after they were placed in the field and before they came within cannon-range of the enemy. Modern wars, however, are conducted on so grand a scale and with such rapidity that they involve all the functions of a government, and definite plans for their conduct must be prepared in advance. Consequently questions of statesmanship and diplomacy are frequently the leading factors in planning campaigns and battles, and thus become strictly strategical considerations. The domain of strategy must therefore be extended to include the methods of organizing and stationing active armies and reserves so that without unintentionally threatening or irritating neighboring countries they can be immediately mobilized for campaign when necessary. Financial and commercial considerations have the greatest possible weight in this connection, and frequently fix the time for beginning hostilities and determine the plan of campaign. In a country with a popular government, in order to arouse enthusiasm and lead the people to make necessary sacrifices, strategy, as defined above, sometimes requires a plan of campaign which, under other circumstances, might not be desirable.

An army in campaign seeks to obtain possession of some point which is known as its objective, which is selected with a view to the injury inflicted upon the enemy by its loss, and the advantages resulting from its capture. The first may be material, moral, or political; the second generally consist in facilities for further advance, better communications, and greater ease in supplying the army. Hence objectives are frequently capitals, large commercial or manufacturing cities, arsenals, river crossings, or railway centers.

The base of operations is that part of a country from which an army draws its supplies. The portion of country between the army and its base which contains the railways, wagon-roads, and water-routes, by which the army advances and receives its supplies, is called its line of operations or its communications. Since the combatants of an army can not be expected to carry with them more ammunition, provisions, etc., than are needed for one battle, the necessity for securing its line of operations from being broken is manifest. Strategical movements very frequently are directed with a view to threatening the enemy's communications and protecting one's own.

A large army covering a very extended front may, by a skillful attack, have one wing destroyed before the other can come to its support. To accomplish or prevent this is another problem in strategy of frequent application. Similar problems arise when a small but concentrated army tries

to beat in detail the parts of a larger one which attempts to concentrate upon a point at or near that occupied by the smaller force, and also in maneuvering to strike a hostile force in flank, in the larger or even in the smaller operations of war.

The guiding principles of strategy consist in so conducting the preliminary operations and movements as to force the enemy to fight at a disadvantage either in numbers, in position, or in the relative results which will follow victory or defeat. The best strategical combinations, however, will not secure victory unless supplemented by the proper handling of the troops in the battle, which is the climax of military operations and which is the field of Tactics (q. v.).

The principles of strategy are best studied in the critical histories of the campaigns of great leaders. See also the *Commentaries of Napoleon*; *Hamley's Operations of War*; *Jomini and Clausewitz on the Art of War*, *La Stratégie Appliquée* Fize, etc. JAMES MERCUR.

Stratford: town; in the county of Essex, England; on the Lea; 4 miles E. N. E. of London (see map of England, ref. 12-J). It has a fine town-hall (1869), several breweries, and manufactories of chemicals and carriages. Pop. (1891) 42,982. On the other side of the Lea is the parish of Stratford-le-Bow. Pop. (1891) 40,378.

Stratford: post-village; capital of Perth County, Ontario, Canada; on the river Avon, at the crossing of Grand Trunk Railway and its Buffalo and Goderich Division (see map of Ontario, ref. 4-C). It has extensive repair-shops, a fine railway-station, good water-power, extensive manufactures, and a town-hall. It is an inland port of entry. Pop. (1891) 9,501.

Stratford de Redcliffe, STRATFORD CANNING, Viscount: diplomatist; b. in London, Nov. 4, 1786: was educated at Eton and Cambridge; in 1807, while still an undergraduate, received diplomatic appointments and did not take his degree till 1812. In 1814 he was sent as minister to Switzerland, in 1820 on a special mission to the U. S., in 1824 to Russia, and in 1825 as ambassador to Turkey. Diplomatic intercourse having been interrupted by the naval battle of Navarino, he returned to England and subsequently sat in Parliament for Government boroughs until 1842, when he was again sent as ambassador to Turkey, retaining that position till 1858, during which time his influence at the Ottoman court was very great, and always exercised in favor of reforms, especially those involving the amelioration of the condition of the Christian population of Turkey. The most interesting point of his whole career was the contest between him and Prince Menchikoff, in 1853. The question was whether British or Russian influence should prevail in Constantinople—or, rather, whether Russia should be allowed to settle the future destinies of Turkey to her own advantage and without paying any regard to the views of the other European powers. The keenly contested diplomatic struggle between Lord Stratford and the Russian ambassador extraordinary—the result of which was the Crimean war—is narrated with dramatic power by Mr. Kinglake in his *Invasion of the Crimea*. Canning was raised to the peerage in 1852 by the title of Viscount Stratford de Redcliffe, and made Knight of the Garter in 1869. He published an essay, *Why am I a Christian?* (1873), and a drama, *Alfred the Great in Athelney* (1876). D. Aug. 15, 1880. See his *Life*, by Stanley Lane-Poole (1888).

Stratford-on-Avon: town; in Warwickshire, England; 8 miles S. W. of Warwick; on the Avon, which is here crossed by a bridge with fourteen arches built in the fifteenth century (see map of England, ref. 10-II). The house in which Shakspeare was born is still preserved; that in which he died has been razed. The former, which is a Shakspeare Museum, and Anne Hathaway's cottage, are national property. The parish church is a cruciform structure rebuilt 1332-1500. In the chancel, restored 1890-92, Shakspeare was buried. Pop. (1891) 8,318.

Strathclyde: an independent kingdom formed in southwestern Scotland at the dissolution of the ancient Brittonic confederacy, and consisting chiefly, as its name imports, of the broad valley or dale of Clyde. The capital was the fortress of Alclyde, now Dumbarton. The annals of its sovereigns are involved in deep obscurity, little more than their names being known. It fell to the crown of Scotland early in the twelfth century, was held for some years by Prince David as an independent kingdom, and was permanently united to Scotland on his accession to the throne in 1124.

Strathmore', or **The Great Valley**: the most extensive plain in Scotland; stretches across the country from Dunn bartonshire, to the S. W., to Strathaven, in Kincardineshire, to the N. E. It is bounded N. by the great mountain range of the Highlands, and S. by the Lothians, the Tweed, and the Midway hills, and is divided for the most part by the Tay, the longest and largest river of Scotland. The whole tract, which is highly cultivated, is about 100 miles long, and from 5 to 10 miles broad. Perth stands near its center, and to this central part the name is more particularly applied.

Strathmore', **Hon. Henry Ross, Baron**: military; b. in Dorset, Mar. 8, 1801 (his father being British minister there), and entered the British army as ensign in 1820; served in the Syrian campaign (1840-41); was queen's commissioner at the headquarters of the French army in the Crimea war, and was wounded before Sebastopol. Through his Indian military (1857-58) he commanded the Central India field force. His rapid marches and successful actions in the field won for him the thanks of Parliament and promotion to the rank of lieutenant-general 1869. He subsequently succeeded Lord Clyde as commander-in-chief in India, and during his term the Queen's forces were united with those of the East India Company. He commanded the British forces in Ireland 1861-70; was raised to the peerage in 1890 as Baron Strathmore of Strathmore, in the county of Nairn, and of Jhansi, East India; was promoted to be general in 1897, and in 1899 was appointed to succeed Lord Dufferin in the command of the Royal Horse Guards. He became field-marshal in June, 1877. D. in London, Oct. 16, 1893. F. M. Cochr.

Strathpeffer (i. e. valley of the Peffer): village of Ross and Cromarty, Scotland; 20 miles by rail N. W. of Inverness. There are cold sulphur and iron water springs, which are much frequented and are useful in gout, rheumatism, scurf, and diseases of the skin, kidneys, stomach, and liver. The climate is very favorable for the latitude (57° 34' N.), and the surrounding region is picturesque and interesting. See *Vox, Strathpeffer Spa* (1889). M. W. D.

Strathroy': town of Middlesex County, Ontario, Canada; on the river Sydenham, and on Great Western Railway; 49 miles E. of Sarnia and 20 miles W. of London (see map of Ontario, ref. 5-11). It has manufactures of woollen castings, steam-engines, agricultural tools, etc. Pop. (1891) 3,316.

Stratigraphy: See **Geology**.

Stratus: See **Clouds**.

Strauss, **ströus**: the name of a noted family of composers. —**Johann**, the elder, was born in Vienna, Mar. 14, 1804, and in early childhood showed great talent for the violin. After study and experience, became deputy conductor to Lanner. In 1826 he had his own orchestra, and then began writing the waltzes which have since made the name of Strauss known everywhere. It was in 1840 that he conducted for the first time in the Imperial Volksgarten, Vienna. D. Sept. 25, 1849. He had five children. —**Johann**, the eldest son, b. in Vienna, Oct. 25, 1825, succeeded his father as a conductor, and in 1861 became conductor of the court balls. He composed nearly 400 waltzes, and a number of operettas which have had great success. He retired from the conductorship in 1870 to devote himself wholly to composition. —**Joseph**, the next son, b. in Vienna, Aug. 22, 1827, became also a conductor and composer. His works number upward of 200. Died July 22, 1870. —**Edmund**, the third son, b. in Vienna, Feb. 14, 1835, made his first appearance as a conductor in 1853; in 1855 conducted at St. Petersburg, and in 1870 succeeded his brother Johann in Vienna. He has composed over 200 dance pieces. Both Johann and Edmund have visited the U. S. and conducted concerts. D. E. Harvey.

Strauss, **DAVID FRIEDRICH**: theologian; b. in Ludwigsburg, Württemberg, Jan. 27, 1809. His parents lived in moderate circumstances; his chief talent seems to have been inherited from his mother. As a child he was retiring and of weak constitution, but fond of study and thorough in his acquisitions. At an excellent school in Blaubeuren and at the University of Tübingen he pursued his classical and theological course with zeal and independence; Haur was one of his teachers in both places. In philosophy he was at first repelled by Kant, but attracted by Schelling, Jacobi, and the famous German mystic Jacob Böhme, fol-

lowing also with eagerness the new revelations of Hegel and others on "the dark side of nature," and to the sphere of the so-called animal magnetism. In the latter part of his course he was strongly influenced first by Schelling, next, but chiefly by Hegel, whose system and comprehensive system, sufficient, as was supposed, for all things, was just coming into general notice. Schelling's master's lectures on the life of Jesus, which Strauss heard in Berlin in 1821, and Hegel's lectures on the philosophy in the *Lectures on Science*, which, published in 1822 and 1826, 2 vols., in Tübingen, made an epoch in the history of German theology. This work was written in the course of a year, while he was Regent at Tübingen (since 1822), when the author was only twenty-seven years of age. In the learned world of Germany it brought matters to a crisis, both in respect to biblical criticism and the relations of faith to speculation (4th ed. 1840; translated from the 4th ed. into English by Mary Ann Evans (George Eliot), 2 vols., London 1841; n. s., 1 vol., 1891; New York 1893) into French, from the 3d ed. by Lullier, 4 vols., Paris, 1840). Strauss lays down in the preface the general principle that nothing which is supernatural, neither prophecy nor miracle, can be historical. The force of his criticism of details rests on this assumption. He resolves all the supernatural elements of the gospel story into myths; his hypothesis is known as the "mythical theory"—that is, the transforming of popular religious beliefs into facts supposed to have been realized in the life of Christ. The work had the merit of bringing together all the scattered objections to the life of Christ, and shaping them into a theory. But unless the supernatural can and be manifested, the underlying theory falls to the ground. In his concluding essay he applies the Hegelian logic to the life of Christ in such a way that, though he denies the facts as historical, he yet admits that there are certain essential ideas at their basis. Historical Christianity is true, not as history, but as idea. The Hegelian philosophy is to be substituted for Christianity. The work was written in a clear and trenchant style, at once popular and scientific. It was repudiated by some of the most eminent divines in Germany (such as Neander and Tholuck) and in other countries. In 1827-28 Strauss replied to his critics in several *Streitschriften*, and in *Zwei friedliche Bistler* (Albana, 1829). He lost his theological position at Tübingen in full account of the ecclesiastical proceedings, including the letters of Strauss, is given by Weissbach in the *Jahrbücher f. deutsche Theologie*, 1875, 4th part, and became a teacher in Ludwigsburg and Stuttgart. He was called to be professor of dogmatics and church history in Zurich in 1839, but was deprived of his chair by a popular insurrection, though retaining for life half his salary. In 1839 he published in Leipzig a volume on *Charakteristiken und Kritiken, entnehmend ausser aus Soldatenmacher, Dant, und Kerner, on animal magnetism and modern possessions, etc.* In 1841 he was married to a once-celebrated singer, Agnes Schaefer, but their characters, says Zeller, were so incompatible and the marriage so unhappy that they separated by mutual consent after five years. The wife lived in Stuttgart until her decease Dec. 23, 1870. In 1840-41 Strauss attempted in his far theology what he supposed he had accomplished for the life of Christ. Under the title *Die christliche Glaubenslehre in ihrer geschichtlichen Entwicklung, und im Kampfe mit der modernen Wissenschaft dargestellt* (2 vols., Stuttgart, 1840-41) he tried to resolve the whole of theology into philosophy. But this work, though learned and acute, made a comparatively slight impression. Having thus, in his opinion, disposed of historical and dogmatic Christianity, he betook himself for twenty years to general literature, interspersed with political speeches and action, leading the life of a wanderer from city to city. In 1847, at Mannheim, he published a pamphlet, *Der Romantiker auf dem Throne der Chören, oder Julius der Abtrünnige*, an ingenious parallel between Julius the Apostate and King Frederick William IV. of Prussia, made up chiefly of apt and sharp citations. In the revolutionary period of 1848 he failed in an attempt to be elected to the new Frankfurt Parliament, but he was chosen to represent his native town (Ludwigsburg) in the diet of Württemberg, where, to the surprise of his adherents, he denounced democracy, and in his very latest work he takes special pains to disparage republican institutions. His political views are contained in *Sechs Stunden politischer Volkswörter* (Stuttgart, 1849). In 1849 he published *C. F. D. Schubert's Leben in seinen Briefen* (2 vols.). In 1851, at Mannheim, appeared a memorial of one of his friends, Christian Märklin; in 1852, at Frankfurt-on-the-

Main, the *Leben und Schriften des Dichters und Philologen Nikodemus Frischlin*, representing the German culture of the sixteenth century. In 1857 he produced at Leipzig in a more important work, the *Life of Ulrich von Hutten* (2 vols.; an abridged ed. 1871; Eng. trans., London, 1874), prepared for Böcking's edition of Hutten's works; and in 1860 a volume of Hutten's *Conversations*. It was here first that he so highly eulogized and vindicated the German nationality, which he afterward advocated in such a brilliant style in his correspondence with Renan, *Krieg und Friede* (1870). In 1862 he revived the memory of a German rationalist of high critical attainments—a forerunner of Lessing—Hermann Samuel Reimarus. These and other literary and biographical works, all wrought out with æsthetic care, added to his reputation for general scholarship. In 1864 he returned to theology in the attempt at writing another life of Christ under the title *Das Leben Jesu für das deutsche Volk bearbeitet* (Eng. trans., London, 1865). The school of Baur of Tübingen and the progress of historical criticism had effectually supplanted the mythical theory of Strauss's first *Leben Jesu*. His object in the second work is, in general, to show what remains of Christ for the people after German criticism has had its full course; and he still grants that "Christianity is a moral and spiritual power in the earth"; that "we can not do without it, nor can it be lost"; that Jesus "stands foremost among those who have given a higher ideal to humanity." In 1865 he reviewed Schleiermacher's *Life of Christ*, then first published, in a work entitled *Der Christus des Glaubens und der Jesus der Geschichte* (Berlin). In 1866, under the title *Die Halben und die Ganzen*, he criticises the semi-rationalistic theology of Schenkel even more severely than he does the unbending orthodoxy of Hengstenberg. His essays on *Voltaire* (Leipzig, 1870; 3d ed. 1872) were prepared for the Princess Alice, and are praised for their critical skill and elegant diction as standing by the side of Goethe's *Wahrheit und Dichtung*. His last work, *Der alte und der neue Glauben, ein Bekenntniss*, appeared in Oct., 1872. It is intended to give the result of his life's thought and work. It rapidly went through seven editions in Germany, was published in French, and in an English version by Mathilde Blind in London and in New York (1873).

Strauss founded no school, either in philosophy or theology. He was a critic, learned, sagacious, yet without any well-defined ultimate system. His life is a reflex of the most extreme anti-Christian theory of human life. He began as an idealist and ended as a materialist. He gave up his early Hegelian pantheism to the latest theory of atheistic evolution. D. at Ludwigsburg of cancer, after long and patient suffering, Feb. 8, 1874, and was buried, by his own direction, without any church service. His *Gesammelte Schriften*, edited by E. Zeller, appeared at Bonn (12 vols., 1876-78). See his *Life*, by E. Zeller (Bonn, 1874; Eng. trans., London, 1874), and by A. Hausrath (2 vols., Heidelberg, 1876-78).
Revised by S. M. JACKSON.

Straw and its Manufactures [*straw* is O. Eng. *strēaw*; O. H. Germ. *stroh*. > Mod. Germ. *stroh*, connected with *streuen*, Eng. *strew*]: The stalk or stem of certain grains, chiefly wheat, rye, oats, barley, and buckwheat, and sometimes of peas and beans, called straw, finds large use in the manufacture of textile fabrics, paper, and braid for hats and trimmings. Originally, the employment of straw was one of the primitive arts, and it is still practiced among the rudest tribes known. Mats for sleeping on are perhaps the earliest objects that were made from straw. Baskets and bags of braided straw are still common among many aboriginal peoples. Those made in the South Sea islands are so close in texture, though quite flexible, as to be impervious to water, and are used to carry liquids. A higher development of the art is shown in the so-called Panama hats and cigar-cases that are made in South and Central America from the straw of the *Carludovica palmata*. The leaves of this plant, which resemble a palm, are gathered before they unfold, and, after the ribs and coarser veins have been removed, are cut into shreds. These are exposed to the sun and then tied into a knot and immersed in boiling water until they become white, when they are hung up in the shade and afterward bleached. The finest of these Panama hats take several months to make, and come from Ecuador, while commoner kinds are made in a few days. In certain of the U. S., as Florida and Georgia, a domestic straw from some varieties of hair grass was formerly used in making women's hats. Other uses to which straw in its natural state is put include its employment as

littering in stables; as fodder; as filling for mattresses; as thatching for roofs; as packing material for delicate articles, such as crockery, glass, etc.; as bottle-covers; as stuffing, as in saddles; as "straws" in fancy drinks; as sandals; for decoration and ornamentation, as in kindergarten work; or fancy straw frames and baskets. Its use as a fuel has been suggested in the event of the coal-supplies becoming exhausted. It is the fiber from the straw of the flax plant that is largely used in the making of linen. The most important application of straw is probably in paper-making. The crude straw is cut and put into vats with lime. It is then cooked and worked into pulp in a beating-machine. This pulp is run off in a web machine into straw-paper, used in wrapping, etc., or into straw-board, used in making boxes, etc. When bleached it is white. The tissue-paper used in the making of cigarettes is commonly made from straw. The rye straw yields the best qualities of paper. In the form of braid, straw is largely used in the making of hats, and as trimming in millinery. Straw hats were worn by the Romans, but the industry remained in a primitive condition until toward the end of the sixteenth century. It is said that Mary, Queen of Scots, engaged a company of Lorraine straw-plaiters to return with her to Scotland in order to instruct her countrywomen in their art; and thus "was the first straw-hat manufactory established in Scotland under the kind auspices of a female sovereign of eighteen." Notwithstanding her inability to care for the little colony she brought from France, they struggled on until her son James became King of England, and then they were transferred to Luton, Bedfordshire, England. In Italy the chief seat of the industry was in Tuscany, and the Leghorn hats have acquired a high reputation. A grand ducal decree of 1575 enumerates the dealers in straw hats among the Tuscan traders liable to a matriculation tax; but, according to a monumental inscription in the Church of San Miniato at Signa, near Florence, Sebastiano Michelacci di Bologna, who died in 1739, was the first to export straw hats to England, and he is hence regarded as the founder of this branch of national commerce. In Italy, as the making of straw plaits grew, certain straws, methods of treatment, and patterns gave rise to characteristic varieties of bonnets with special braids, as the Tuscan and Leghorn hats which were typical and fashionable. Foreign wars prevented their importation into England, and the Dunstable bonnet of home manufacture was the result. On the restoration of peace unplaited straws, imported from Tuscany, resulted in the Tuscan grass bonnet, one of which was publicly worn by Queen Adelaide. Thus the industry, originally that of the finished product, passed in England into one where various straws, both native and imported, were manufactured into the desired article. This result was somewhat due to the efforts of the British Society of Arts, which made great efforts to sustain the industry. In 1822 it awarded a silver medal and twenty guineas to Miss Sophia Woolhouse, of Connecticut, for a new material for fine plaits, the *Poa pratensis*, then supposed to be equal to the Italian straw for making fine straws. For some time the industry had been in existence in the U. S., and the first straw bonnet braided in the U. S. is said to have been made in 1798 by Miss Betsey Metcalf, of Providence, R. I., but the industry has followed the practice of Great Britain, and now the crude braid is chiefly imported and made up into the various finished products as hats (of which there are 103 factories in the U. S. and Canada). The principal sources of the straw imported into the U. S. are China, Italy, England, Switzerland, Germany, Japan, Belgium, and France. For braid-wheat straw is preferred, but rye straw has longer stems and can be braided into more delicate and even tissues. It is, however, less durable, and does not wash as well as wheat. In Tuscany the preferred straw is from a variety of spring wheat, thickly sown, best on a sandy, hilly ground, in February or March, according to season and local climate, and harvested by pulling the bearded wheat while the ear is in a soft milky state. The straw is left spread upon clean ground or grass for some days for the sake of the action of the dew in bleaching it; it is then gathered into sheaves, from which the laborers draw out the stalks, breaking them at the joints and breaking off the heads. They are then sorted by a species of sieve composed generally of sixteen tin plates pierced with holes and briskly moved by a wheel. They are then plaited and, if for straw hats, are shipped in bales of 240 pieces of 50 meters each. English straws are made into lengths of 20-yard pieces, although sometimes 14 and 12 yard pieces are made. Originally, the "whole straw" was used in plaiting, but in England the splitting of the straw

with a knife led in the production of a lighter variety, and, about 1813, machines were introduced for cutting. This invention is one of the causes of the great success that has attended the manufacture of straw plait in England. Originally, the varieties of straw plait were few, but in recent years an almost endless number of patterns have come into existence, many of which are colored. Notwithstanding the foreign competition, especially that from China, whence the so-called Canton plaits come, London continues to be the chief market of the world, and regular sales are held there. In the U. S. the reeds bridle are used chiefly for straw hats, and they are bleached and sewed into shape. The hats are then finished and stored, after which they are finished by putting on bands, sweatbands, tips, etc. The fancy straw plaits are used in millinery, and are imported ready for use. According to the census returns of 1890 there were six manufacturers of straw goods other than those of hats and caps in the U. S., with an aggregate capital of \$100,793, and employing 491 hands. During 1894 there was imported into the U. S. \$2,002,88 tons of straw, valued at \$97,529.00, also manufacturers of straw not specially provided for, valued at \$981,049.74, and during 1895 straw for drinks valued at \$2,150. Materials for hats, bonnets, bands, etc., including straw, ships, and other bridle, amounting to \$2,050,715.10, were imported during 1894. MARCUS BENJAMIN.

Strawberry [O. Eng. *stresaburige* < primitive Teutonic *stresano* < Indo-Europ. *wehso-*; cf. Lat. *fragosa*; Gr. *ἄβη*. The association of the Eng. word with *stres* is false]; any species of the genus *Fragaria*, family *Rosaceae*. The genus is a small one, comprising under a liberal estimate about a dozen species, and it is confined to temperate climates of both the northern and southern hemispheres. The species are all low herbs with three-divided leaves, propagating by runners, and bearing the flowers and fruits upon short scapes. Botanically considered, the strawberry fruit is a fleshy receptacle or stem, upon which the true fruits or achenes—generally called seeds—are borne. The strawberry is a fruit of comparatively recent cultivation; the first named garden variety having appeared in 1660. At the present time it is largely grown, and in North America it exceeds in importance any other of the small fruits. Commercial strawberry-culture began in the U. S. about 1800. The first important variety of American origin was the Hovey, which first fruited in 1830 or 1837 in the garden of the originator, Charles M. Hovey, Cambridge, Mass. This was followed in importance by Boston Pine. About twenty years after the Hovey appeared, the Wilson, or Wilson's Albany, was introduced from the garden of James Wilson, Albany, N. Y., and this variety is still the most popular market berry in many parts of the Northern States. These varieties, and all other commercial strawberries of North America, are offsprings of the old Pine strawberries, a class which sprung from the Chilean berry (*Fragaria chilensis*). This species was first introduced into Europe about 1712, by Capt. Pualet. The evolution of the garden strawberries from this type has taken place mostly within the nineteenth century. The wild strawberry of the eastern parts of the U. S. (*Fragaria virginiana*) was early introduced into Europe, and it was once the leading type of garden strawberries, but it is now practically lost to cultivation. The Haulbois strawberry (*Fragaria moschata*), and the Alpine and Perpetual types (*F. elsa*), both of Europe, are occasionally cultivated by amateurs.

In the U. S. the strawberry succeeds in a great variety of soils, but, in the North, at least, the best soil is thought to be a rich sandy loam, particularly one which resists the effects of drought. The methods of planting and cultivation are various, but all strawberry-growers agree that the plants are not profitable after they have borne three crops. There is an increasing tendency to allow the plantation to bear but a single crop, for, if the ground is good and the treatment generous, the first crop is the best which can be obtained, and the frequent rotation prevents the land from becoming foul, and it effectually prevents various mischief from the leaf-rot fungus and from various insects. Early spring is the time usually preferred for setting the plants, and the first crop is borne a year from that time. If the plants bloom to any extent the year they are set, the blossoms should be removed, in order to allow the plants to become thoroughly established for the following year's crop. Strawberries are commonly planted in rows from 34 to 5 feet apart, and the plants are set from 1 foot to 2 feet apart in the row. It is customary to allow the plants to form a

mat or continuous row a foot or 2 feet wide, although, in private gardens, hill-culture is sometimes practiced for the purpose of securing finer fruit. In the northern parts of the U. S. the plants are generally sowed late in fall with a light sowing of straw or marsh hay, as a protection against frost. Most persons leave this sowing upon the ground until the crop is harvested, drawing it off the plants into the spaces between the rows as soon as growth begins in spring. Some varieties of strawberries have flowers without runners, and these must be planted near pollen-bearing varieties to insure fruitfulness. The best method of planting is as to insure perfect pollination, varies with the varieties and with the grower, but it is generally thought that at least one-third of the plants should be strong pollen-bearers. An average good yield of strawberries may be considered to be from 150 to 250 bush. per acre. There are various insect depredations and other troubles, for an account of which the reader should consult the bulletins of experiment stations. The varieties in favor change so frequently that no list of them can be recommended here. There are many good writings upon the strawberry. The fullest account of American varieties is to be found in Merriell's *Strawberry and its Culture* (1870). A philosophical discussion of the origin of the cultivated strawberries, by Bailey, occurs in *The American Naturalist* (xviii: 293, Apr., 1894). The reader should consult Bailey's *Strawberry Culture*, and Terry and Root's *How to Grow Strawberries*. L. B. BAILEY.

Strays: See **STRAY**.

Streator: city (laid out in 1898, incorporated as a city in 1899); La Salle co., Ill.; on the Vermilion river, and the Atch. Top. and R. R., the Earl, Route, the Chi. and Alton, the Ind., Ill. and Ia., and the Wabash railways; 93 miles S. W. of Chicago (for location, see map of Illinois, ref. 8-15). It is built on the river bluffs, and has adequate sewerage, gas, electric-lighting, street-railway, water, and fire services, and an improved public park of 11 acres in the heart of the city. It is surrounded by a rich agricultural country, and is underlaid by several seams of coal, two of which are being worked, and also by valuable strata of shale, fire-clay, and other clays, which are used in making paving-bricks, sewer-pipe, and other clay products. The city contains 33 churches, including a Greek Catholic church and the unique Church of Good Will toward Men, 17 public schools, a high-school building (the gift of a private citizen, cost \$45,000), 2 kindergartens, 4 private and parochial schools, 2 convents, public library, Y. M. C. A. building with hall, gymnasium, and free reading-room, Planch Opere-house, 8 national banks with combined capital of \$250,000, 3 building and loan associations, 32 fraternal societies, and 9 daily and 3 weekly newspapers. In 1894 the estimated property valuation was \$12,000,000. The industrial establishments include 8 day-working factories, machine building and paving works, sewer-pipe, and tile; several manufacturers of glass bottles, window glass, rolled plate-glass, flint and Bohemian ware, and glass specialties; foundries and machine-shops, and flour and planing mills. Pop. (1880) 5,157; (1890) 11,414; (1894) estimated, 15,000. J. E. WILLIAMS.

Street, GEORGE EDWARD, R. A., F. S. A.; architect; b. at Woodford, Essex, England, June 20, 1824; was educated at Cambridge, and afterward studied architecture under Gilbert Scott. In 1850 he was appointed architect for the diocese of Oxford, and subsequently for those of York, Ripon, and Winchester. His predilection was mainly for the Gothic style, and he was recognized as one of the leaders in the Gothic Revival (q. v.). His architectural structures are very numerous and important; among them are SS. Philip and James, Oxford; the Crimean Memorial church, Constantinople; and the Synod House in Dublin. Among his restorations are Jesus College chapel, Cambridge, and the nave and choir of Christ Church Cathedral, Dublin. In 1847 he won one of the £100 prizes for a design for a new Foreign Office, and in 1868 was appointed architect of the buildings for the new courts of law, but his original design was afterward considerably modified. Besides numerous essays and lectures upon architecture, he published *The Brick and Marble Architecture of North Italy in the Middle Ages* (1855) and *Some Account of Gothic Architecture in Spain* (1865), which latter work is of peculiar value as being the only concerted account of the interesting cathedrals and other churches of the Peninsula. D. Dec. 18, 1891.

Revised by HERBERT STUART.

Street-railways: railways constructed wholly or chiefly in the streets of cities or towns, and designed especially for

local passenger traffic. The first application of the railway to the facilitation of short-distance passenger traffic in towns was made by John Stephenson in New York in 1831. A track of flat iron bars spiked to timbers resting on stone blocks was laid on the Bowery and Fourth Avenue from Prince Street to the Harlem river. An omnibus car, with flanged wheels and built in three compartments entered from the side and each holding ten persons, and with seats on the roof for thirty more passengers, was drawn by horses. Commercially this enterprise was not successful, and was abandoned after four years, but was resumed in 1845 with cars of the form used at present, entered from the ends. In 1852, the Second, Third, Sixth, and Eighth Avenue lines in New York were begun. Boston began the construction of horse-car lines in 1856, Philadelphia in 1857, and New Orleans in 1861, using for the first time the one-horse small car usually known as the "bob-tail." In France a line was constructed in Paris in 1853. In Great Britain George Francis Train, after three years of earnest endeavor, succeeded in 1860 in building a road at Birkenhead and one in London, which was removed in a few months, and not until 1870 were horse-cars permitted in that city. In 1866 a number of horse-car lines were built in South America.

The passage of the General Tramways Act by Parliament in 1870 gave an impetus to street-railway construction in Great Britain, and during the following twelve years 671 miles of lines were laid.

In 1894 there were in operation in the U. S. 12,500 miles of street-railway track, in the United Kingdom 1,000 miles, and on the continent of Europe 1,200 miles. There were also lines in Africa, Japan, Australia, New Zealand and Ceylon, and South America.

Prior to 1873 all street-cars were drawn by horses. In that year Andrew Hallidie constructed a road in San Francisco, Cal., on which the motive power was provided by a stationary steam-engine which drove a drum, around which passed an endless wire cable which was carried in pulleys in a conduit underneath the surface of the street on which the rails were laid. Through a slot in the top of the conduit a flat bar passed from the car to the cable, fitted with apparatus for grasping the cable tightly or releasing it at will, which could be controlled from the car. After several years of successful operation of this mode of propulsion in San Francisco, it was introduced in Chicago in 1881, in Philadelphia in 1883, on the Brooklyn bridge in the same year, on Tenth Avenue and 125th Street in New York in 1886, and on Broadway and Third Avenue in 1894, and in Baltimore in 1893. A cable road was built in New Zealand in 1883 and one in London in 1884. In 1894 there were 662 miles of cable road in operation in the U. S., and 20 miles in England.

The first commercially successful application of electricity to the traction of street-cars was made at Lichterfelde, near Berlin, by Siemens and Halske in 1881. On July 27, 1884, the first operation of an electrically propelled line in direct competition with horse-cars was begun at Cleveland, O., on the Bentley-Knight system. In the same year the first practical system of conveying the electricity from wires overhead to a motor on the car by a trolley, or small grooved pulley on the end of a flexible pole extending above the roof of the car, was made in Kansas City, Mo. Improvements in the apparatus made by Sprague in 1888 led to the construction of the first installation on a large scale of an electrically propelled street-car system at Richmond, Va., in that year. The greater economy and efficiency of electric roads was quickly recognized, so that while in 1888 there were 89 miles of roads so operated, there were in 1894 9,008 miles in the U. S. and 195 miles in Europe. For description of the system, see ELECTRIC RAILWAYS.

In 1881 Mekarski applied compressed air with success as a motive power to street cars at Nantes, France, and the same method has since been applied in Paris and in Berne, Switzerland.

The desire for more rapid transit between distant points in large towns than is safe in a street used by pedestrians and vehicles drawn by horses has led to the construction of lines of travel above and below the surface of the ground. The first effort in this direction was in London in Jan., 1863, when a 3-mile section of underground railway was opened for traffic. Its success led to the extensions of the line until 1884, when 15 miles of line were completed. In Dec., 1890, another underground road, the City and South London, 3 miles long and operated by electricity, was

opened for travel. In Berlin a viaduct carrying railway tracks above the street-level for 7½ miles through the center of the city was opened in 1882. In New York an elevated railway, 4 miles long, supported on columns on the sidewalk of streets, was put in operation in June, 1869, operated by a cable. This was unsuccessful, and locomotive engines were substituted on Apr. 9, 1871. In 1877 additional lines were built, until in 1879 there were 32¼ miles in operation on Manhattan Island. Between 1886 and 1891 the Suburban Rapid Transit Railroad was built, extending the system 3·7 miles N. of the Harlem river, and introducing improved methods of construction and heavier rolling stock. In Brooklyn, in 1885, an elevated road was put in operation, and in 1895 there were 25 miles in operation. In 1893 an elevated railway, 5 miles long, was opened in Liverpool, England, operated by electricity.

The relative cost of building and equipping each mile of double-track railway for the different methods of traction, the rate of speed attained, and the expense of running a car a mile, are approximately as follows:

MOTIVE POWER.	Cost per mile.	Speed, miles per hour.	Operating expenses per car-mile.
Horses	\$71,000	6	18 cents.
Cable	800,000	10	14 "
Electric surface	115,000	12	13 "
Steam elevated	500,000	13	13 "
Underground	1,500,000	13	15 "

Streitberg, strit'bärch, WILHELM: comparative philologist; b. at Rüdeshelm, Germany, Feb. 23, 1864; educated at the gymnasium in Wiesbaden and at the University of Leipzig; docent at Leipzig 1889, and in autumn of same year Professor of Indo-European Philology in the University of Freiburg in Switzerland. He is one of the most aggressive of the younger generation of comparative philologists. He is the author of *Die Abstufung der Suffixe in und ieu im Germanischen* (1888); *Perfective und imperf. Aktionsart im Germ.* (1889); *Die germ. Komparativa auf -iz* (1890); *Zur germ. Sprachgeschichte* (1892); *Entstehung der Dehnstufe* (1894); joint editor with K. Brugmann of *Indogermanische Forschungen* since 1891. BENJ. IDE WHEELER.

Strength of Materials: the resistance of materials to forces which tend to change their form; often called the elasticity and resistance of materials. The science of the strength of materials is sometimes called the mechanics of materials. The subject is partly experimental and partly theoretical, the experiments furnishing the fundamental facts, while the application of theory to these deduces the rules and formulas for practical use.

The materials used in engineering constructions are more or less elastic when the applied forces are not too great, that is, they spring back to their original form upon the removal of these forces. For elastic materials it is found that the change of form is proportional to the applied force; this law holds until a point called the elastic limit is reached, after which the change of form increases more rapidly than the force, and rupture finally occurs. It is a fundamental rule in engineering that materials should not be strained beyond the elastic limit, since then the elasticity is impaired and a permanent deformation results.

The molecular resistance which is developed by an applied force is called stress. Stresses are tensile when the forces tend to pull a body apart, compressive when they tend to crush it, and shearing when they tend to cut it across. In bending a beam stresses are produced often called flexural, but they can always be resolved into those of tension, compression, and shear; in twisting a shaft stresses are produced often called torsional, but they can also be resolved into the three kinds of simple stress.

Tension.—When two equal forces are applied at opposite ends of a bar or rod a tensile stress equal to one of the forces is produced at every cross-section of the bar. If P be the intensity of each of the forces then the internal stress is also P . If A be the area of the cross-section of the bar the unit-stress is $P \div A$, and this is represented by S . Unit-stresses are usually expressed in pounds per square inch or in kilogrammes per square centimeter. If the force P be gradually applied the unit-stress S also gradually increases, and is accompanied by an elongation of the bar. When P is large enough to cause the rupture of the bar the unit-stress S is called the ultimate tensile strength of the material. The elastic limit is reached for some materials when the unit-

stress is about one-half the ultimate strength; when S is less than this elastic limit the bar springs back to its original length upon the removal of the applied forces; when it is greater it does not entirely spring back, but a permanent set remains.

If l be the original length of the bar and λ the elongation produced at any stage of the test, $\lambda + l$ is the unit-elongation. Within the elastic limit the ratio of the unit-stress to the unit-elongation is called the coefficient of elasticity, or sometimes the modulus of elasticity. Let s be the unit-elongation, and E the coefficient of elasticity; then

$$E = \frac{S}{s} = \frac{Pl}{A\lambda},$$

and the value of E is sensibly a constant for any simultaneous values of S and s , provided that S is less than the elastic limit.

The following are average values of the tensile elastic limit, ultimate strength, coefficient of elasticity, as also the elongation at the elastic limit and the ultimate elongation, for four principal materials used in engineering:

MATERIAL.	POUNDS PER SQUARE INCH.			ELONGATION. PER CENT.	
	Elastic limit.	Ultimate strength.	Coefficient of elasticity.	At elastic limit.	At rupture.
Timber.....	3,000	10,000	1,500,000	0.20	1.5
Cast iron.....	6,000	20,000	15,000,000	0.04	0.5
Wrought iron.....	25,000	55,000	25,000,000	0.10	25.0
Steel.....	50,000	100,000	30,000,000	0.17	15.0

These values are subject to much variation, particularly for steel, which may range from 60,000 to 300,000 lb. per square inch in ultimate strength. Iron wire has an ultimate strength of nearly 100,000 lb. per square inch, and cast iron has been made with a tenacity of 46,000 lb. The strongest kinds of timber, as box, ash, and beech, reach nearly 20,000 lb., while weaker kinds, like poplar and white pine, may be only 4,000 or 5,000 lb. per square inch in ultimate strength.

The diagram in Fig. 1 gives graphical representations of the average tensile properties of these four materials. The stresses per square inch are laid off as ordinates and the percentages of elongation as abscissas, and for any point on one of the curves the approximate values of these two quantities are seen by inspection. The curve for each material is a

FIG. 1.

straight line from the origin until the elastic limit is reached, the unit-stresses being proportional to the elongations. At the elastic limit a sudden change in the curve is noted, and then the elongation increases more rapidly than the stress. The area between the curve and the base is a measure of the work required to rupture a cubic unit of the material.

As the elongation of a bar increases under tension a lateral contraction ensues, the unit-contraction being about one-third of the unit-elongation until the maximum strength is reached, and then, for ductile materials, the contraction increases very rapidly owing to the flow of the metal. The amount of ultimate contraction of area, which often amounts to 50 per cent. of the original area, is regarded as a valuable index of ductility and toughness.

Compression.—The phenomena of compression are similar to those of tension, provided that the elastic limit be not exceeded, and that the length of the bar does not exceed about

five times its least diameter. Rupture usually occurs by cracking and shearing, or sometimes by lateral bulging. The following are average values of the compressive elastic limit, ultimate strength, and coefficient of elasticity for the six principal materials used in engineering constructions, all in pounds per square inch:

MATERIAL.	Elastic limit.	Ultimate strength.	Coefficient of elasticity.
Timber.....	3,000	8,000	1,500,000
Brick.....	4,000
Stone.....	6,000	6,000,000
Cast iron.....	6,000	90,000	15,000,000
Wrought iron.....	25,000	55,000	25,000,000
Steel.....	50,000	150,000	30,000,000

It should be noted that these average values are subject to much variation in different qualities of materials. For instance, the strength of some kinds of brick may be as low as 1,000 and of others as high as 15,000 lb. per square inch; that of some kinds of building-stones may be as high as 20,000 lb. Cast steel has been made with an ultimate compressive strength of nearly 400,000 lb. per square inch. The figures given hence should be used with caution in particular cases.

When the length of a bar or column is less than ten times its least diameter the compressive force P may be regarded as uniformly distributed over the cross-section A , so that the unit-stress S is simply P/A ; but for greater lengths a lateral flexure of the column occurs so that the compressive stress on the concave side is greater than that on the convex side. If C denote the greatest unit-stress on the concave side, l the length of the column, r the least radius of gyration of the cross-section, then

$$C = \frac{S}{1 - \frac{nSl^2}{\pi^2 Er^2}},$$

in which S is the mean unit-stress P/A , and n is a number depending on the arrangement of the ends of the column, being 1 when both ends are round, $\frac{1}{2}$ when one end is round and the other fixed, and $\frac{1}{4}$ when both ends are fixed.

Shearing.—A shearing stress occurs whenever two equal forces, acting like a pair of shears, tend to cut a body apart. When a hole is punched through a plate the ultimate shearing strength of the material must be overcome over the cylindrical surface of the hole. When a rivet connects two plates that are in tension the plates tend to shear the rivet across.

The ultimate shearing strength of timber is about 3,000 lb. per square inch across the grain and only about 500 lb. parallel with the grain; for cast iron it is about the same as the tensile strength; for wrought iron and steel perhaps one-fifth less than the tensile strength. Little is known regarding the elastic limit in shearing, but the coefficient of elasticity is between one-half and one-third of that for direct tension.

A shearing stress is always developed in an oblique section of a bar which is subject to direct tension or compression. If S be the tensile or compressive unit-stress the maximum shearing unit-stress is $\frac{1}{2}S$, and this occurs in a direction making an angle of 45 degrees with the axis of the bar. Shearing stresses also occur in all cases of the bending of beams and the torsion of shafts.

Working Stresses.—The unit-stresses which should be used in the design of structures are much less than the ultimate strength of the material, and indeed less than the elastic limit. The ratio of the ultimate strength to the working unit-stress is called the factor of safety, and the following are average values of the factors of safety usually employed in cases of design:

	Timber.	Brick and stone.	Cast iron.	Wrought iron.	Steel.
For steady stresses.....	8	15	6	4	5
For varying stresses.....	10	25	15	6	7
For shocks.....	15	30	20	10	15

Steady stresses occur in buildings, varying stresses in bridges, while shocks are liable to occur in machinery and on railway wheels and rails. The injurious nature of shocks requires a high factor of safety, and hence a low working stress. A load suddenly applied theoretically produces twice the stress caused by the same load when applied gradually, and the elongation is also double. When a load

drops upon a bar the resulting stresses and deformations are often more than double those caused by a gradually applied load. In all cases it is desirable that such a factor of safety should be used that the maximum working unit-stress may not exceed one-half the elastic limits of the material.

Repeated stresses beyond the elastic limit cause a change of molecular structure, or as commonly expressed, the material becomes fatigued. The greater the range of stress the less should be the working unit-stress used in the design. Stresses alternating from tension to compression require almost double the material that is necessary when the range is in tension alone, and nearly four times as much as for the case of steady stress.

Testing-machines.—The most common method of testing is by tension, the quantities determined being the elastic limit, maximum or ultimate strength, ultimate elongation, and contraction of area. Fig. 2 shows the form of specimen generally used, the heads being clamped in blocks to which the pulling force is applied. Marks are made at regular intervals along the specimen, and measurements made between these, both before and after the test, give the data for computing the elongation. The diameter of the specimen is usually about half an inch, and its length between the heads about 8 inches.

FIG. 2.

The numerous forms of testing apparatus may be classified as screw machines and hydraulic machines, the power being applied in the former by a screw and wheel, and in the latter by pressure transmitted through oil by means of a pump. Fig. 3 shows a machine of the latter class for testing wire and small rods. The wire clamped in position is seen in the foreground. The handle of the pump is worked by hand-power, and the pressure thus produced is transmitted through the oil by means of a small tube to the cylinder above the specimen, where it acts upon a piston which causes the cross-head to move up, and thus brings tension upon the specimen. A scale and weights are provided for reading the tensile stress applied. This machine is 4 feet high, nearly 4 feet long, weighs 890 lb., and can exert a tension of 10,000 lb.

Probably the best and most precise testing-machine in the world is that constructed for the U. S. Government by

FIG. 3.

A. H. Emery, and now at the Watertown arsenal; it has a capacity of 1,000,000 lb., and can break a bar 30 feet long. Special machines of greater capacity have been constructed for testing eye-bars and other bridge members. The machine of the Union Bridge Company, at Athens, Pa., has a capacity of 1,224,000 lb., and it can break a bar 40 feet long. That of the Phoenix Bridge Company, at Phoenixville, Pa., built in 1893, has a capacity of 2,160,000 lb., and it can break a bar 45 feet long.

Compressive tests are more difficult to make than tensile ones, on account of the greater labor of preparing the specimens, and of insuring a uniform distribution of pressure over the surfaces. Even for a material like cement, which is always used in compression, the tensile test is preferred. Flexural tests of beams are often made to determine the modulus of rupture. (See FLEXURE.) Tests for the resistance of specimens to twisting are easily made by the machine devised by Thurston in 1873, which furnishes an autographic record of the stress and deformation, and thus renders possible a thorough study of the properties of materials under TORSION (*q. v.*).

Resilience of Materials.—When a body falls from a height upon a bar or beam it expends an amount of energy equal to the product of its weight and height of fall. This energy is resisted by the work of the internal stresses in the bar or beam. All the work of these internal stresses is called resilience, which is thus a measure of the capacity of the bar or beam to resist shock. Resilience is proportional to stress and deformation jointly. Elastic resilience is the work that can be resisted up to the elastic limit, and ultimate resilience is the total work up to the point of rupture, the latter being far greater than the former. The elastic resilience for different materials in tension can be compared by taking half the product of the elastic limits by the corresponding elongations; this quantity is often called the modulus of resilience. The ultimate resilience of materials can be roughly compared by the areas included between the curves in FIG. 1 and the base. The following mean-values of these quantities for tensile resilience are in inch-pounds per cubic inch of material:

MATERIAL.	Elastic resilience.	Ultimate resilience.
Timber.....	3	100
Cast iron.....	1	70
Wrought iron.....	18	13,000
Steel.....	42	12,000

The laws of elastic resilience show that the total resilience of a bar or beam is proportional to its volume, and independent of the form of cross-section, so that a beam resists shock with equal efficiency whether struck on the narrow or broad side; also the effect of a blow at the middle of a beam is no greater than at any other point. These conclusions are approximately true for ultimate resilience only in the case of cast iron; for other materials the laws are yet to be determined.

History and Literature.—The study of the strength of materials began with the announcement by Robert Hooke in 1678 of the law of proportionality between stress and elongation. Few experiments of value were made, however, until after the beginning of the nineteenth century. The work of Tredgold and Hodgkinson, prior to 1850, has since been extended by Kirkaldy, Bauschinger, Wöhler, Thurston, Howard, and others, so that volumes would be required to give even a fair summary of the properties of the numerous qualities of iron and steel. The strength of alloys of copper, zinc, and tin has been fully investigated by Thurston. Most valuable work was done by the British Government in 1848, and by a U. S. board in 1876. Numerous testing-laboratories have been established by manufacturers and by technical schools, and progress in the knowledge of materials is rapid and continuous.

The theory of the resistance of materials is intimately associated with that of beams, columns, and shafts. Beams were first discussed by Galileo in 1638, and during the nineteenth century the theory of all branches of the subject has been developed by Navier, Poncelet, Saint-Venant, Lamé, Weyrauch, Rankine, and many others. Todhunter and Pearson's *History of the Mathematical Theory of Elasticity and of the Strength of Materials* (London, 1893) gives a full account of these researches. Thurston's *Materials of Engineering* (3 vols., New York, 1884) and Burr's *Elasticity and Resistance of Materials* (New York, 1888) may be consulted for experimental results; Unwin's *Testing of Materials* (London, 1890) and Abbott's *Testing-machines* (New York, 1885) for the methods of conducting tests. Concerning beams and columns, reference is made to the article FLEXURE, and concerning shafts to the article TORSION. See also BRICK, BUILDING-STONE, CEMENT, CONCRETE, and FATIGUE OF MATERIALS.

MANSFIELD MERRIMAN.

Strepsiptera [Mod. Lat.; Gr. *στέψις*, aorist of *στέπειν*, twist + *πτερόν*, wing]: a group of insects, formerly considered

in separate orders, but now classed with the *Coleoptera* as a family, called *Strepodidae*. The elytra are very short, the wings of the male large and folded like a fan (whence the name); the females are wingless. The eyes are large; the legs two to four jointed. They are parasitic on various species of trees and wasps, and are found between the joints of the abdomen. The female never leaves the host, but the winged males become free when mature. K. A. REED.

Streptoneura [From *Str.*, *strepsis*, twisted, a wring, nerve;] a term sometimes employed for a group of molluscs, including the *Prochlamys*, in which the pleuroventral nervous system is crossed in the general twisting of the body. See *ELIOTRODIA*.

Stress [M. Eng. *stress*, probably abbrev. of M. Eng. *distress* > *King, distress*] (a term of phonetic denoting the force in the outpush of breath accompanying the production of one syllable, as compared with others); i. e. relative force. It is commonly attended in English by elevation of pitch, and these two features are often confused under the name *accent*. Whispering, inasmuch as it admits of no variation of pitch, affords a good device for isolating and observing the element of stress. See *ACCENT*. BENJ. LEE WHEATON.

Stresses: molecular resistances which arise in a body when exterior forces are applied to change its form. Forces which cause an elongation of a body are resisted by tensile stresses, those which cause a shortening by compressive stresses, and those which tend to cut apart a body by shearing stresses. The three kinds of simple stress are tension, compression, and shearing, while complex stresses of flexure and torsion are caused by bending and twisting forces.

Stresses are proportional to the changes of form caused by the exterior forces until their magnitude reaches the elastic limit of the material. Beyond this they increase less rapidly than the changes of form, and when the ultimate strength of the material is reached rupture occurs. In engineering constructions it is a general rule that materials should not be stressed beyond their elastic limit.

The determination of internal stresses caused by applied forces is effected by the application of the principles of mechanics, the stresses and forces forming a system of equilibrium to which the fundamental principles of statics apply. If a load of W pounds stretches a rope or bar whose cross-section is A , the total stress in the bar is W , and the stress per unit of area is $P = W/A$. Similarly, in a case of simple compression or shearing, the resisting stress is equal to the applied force. In the simple roof truss shown in the diagram a weight W placed at the peak causes stresses in the two rafters and in the tie-rod AB , whose magnitudes are represented by the corresponding parallel lines in the parallelo-

gram of forces. The vertical reaction of each support is $\frac{1}{2}W$, and the moment of the stress in the tie-rod with respect to the peak is equal to the moment of the reaction with respect to the same point, or if S be the stress, l the length of AB , and h the height of the peak, then $S \times h = \frac{1}{2}W \times \frac{1}{2}l$, whence $S = \frac{Wl}{4h}$, which is a tensile stress. The stress in

each rafter is compressive, and its value is $\frac{W\sqrt{P^2 + 4h^2}}{4h}$.

These expressions show that the stresses increase when h decreases. See *MECHANICS*, *MOMENT*, *STATICS*, *STRENGTH OF MATERIALS*, and *TRUSS*. MANFIELD MERRICK.

Stretton, HENRY: See *SMITH, HANNAH*.

Stretland, ALICE: biographer and historical novelist; b. at Reydon Hall, Suffolk, England, Aug. 19, 1896; with her four sisters was carefully educated under the care of her father, and commenced her career of authorship at an early age, in most of her works being assisted by one or the other of her sisters. Her first work, in conjunction with her sister Susanah, was a volume of *Patriotic Songs*, which was followed by *Worcester Field*, an historical poem. Her next

work, also a poem, was *Demetrius: a Tale of Modern Times* (1897), followed by *The Pilgrims of Walsingham*, an historical romance (1900), and at intervals by many other volumes of biography, poetry, and fiction, among which are *Queen Victoria from her Birth to her Death* (1901); *Historical Novels and Poetic Fancies* (1903); *Lives of the Hanover Kings of England* (1903); *Lives of the Seven Bishops* (1905); and *Lives of the Tudor Princesses* (1906). Her most important works, both prepared in conjunction with her sister Elizabeth, whose name, at her own desire, did not appear as author, are *Lives of the Queens of England* (12 vols., 1840-49; new ed., 6 vols., 1904-05; abridged ed., 1907) and *Lives of the Queens of Scotland* (3 vols., 1850-59)—works based wholly upon original documents. She also put forth a collection of the *Letters of Mary, Queen of Scots*, with an historical introduction and notes (1812-18; new ed., with considerable additions, 3 vols., 1864). In 1870 she received a pension of £100 in consideration of her long and valuable literary services. D. at Reydon Hall, July 6, 1874. See *Life* by her sister Jane (1887).—Her sisters, SUSANAH (Mrs. Moodie) and CAROLINE (Mrs. Trail), removed to Canada, and published works illustrative of life in the Dominion. Revised by U. A. DUFFY.

Stricture [From Lat. *strictura*, a compression, don't, of *stringere*, *stringere*, draw tight, squeeze] (a constriction or compression of some tubular passage of the body, as the oesophagus, the larynx, the windpipe, the intestines, the urethra, the lacrimal ducts, and others. Strictures are produced either by new formations on the inside of the tubes, or by pathological changes in the walls and mappings of the same (degeneration), or by the pressure of new formations or of atrophies outside. Examples of the first class are croup and diphtheria, which by deposition of fibrous masses on the interior of the larynx and the windpipe narrow these organs sometimes to suffocation. A stricture of the third class is frequently produced in the oesophagus by a neighboring cancer, which may compress it to impermissibility. The most frequent strictures are those of the urethra; they are generally produced by pathological changes in the wallings of the organ. Injuries of the perineum and the penis, with or without rupture of the urethra, may originate them, but their most general cause is inflammation of the mucous lining of the urethra, gonorrhoea. Inflammation, if it spreads a little beyond the mucous lining, gives rise to new formation of connective tissue, which either directly compresses the urethra, forming a callous ring around it, or contracts it by atrophic degeneration around the tube. The immediate consequences of urethral stricture are symptoms of impediment to free micturition. The urethra behind the stricture is dilated by the pressure of the accumulated urine. The bladder is not thoroughly emptied, and undergoes inflammatory irritation by chemical decomposition of its contents. The urine becomes alkaline, with a putrid and pungent smell of ammonia. The desire to urinate is very great, and never ceases. In more advanced stages the urine sometimes breaks through the wall of the urethra behind the stricture, and either makes a fistula by breaking also through the skin, or infiltrates the surrounding tissue, and so causes uremia, and often death. In other cases, inflammation of the bladder extends to the kidneys, and there produces pyelitis and inflammation of the kidney proper. Strictures sometimes close up the urethra entirely, or become so narrow that the urine can be passed only in single drops by the strongest and most painful efforts. Speedy relief by operation is necessary in such cases to save the life of the patient. The treatment of stricture consists either in gradual dilatation or in external or internal urethrotomy. Gradual dilatation is effected by inserting bougies, or catheters, or sounds of increasing size. Every day or less frequently a larger instrument is passed through the stricture to the bladder, until the normal size of the urethra is attained. After this the last bougie is used occasionally for some time to prevent a relapse. The majority of authorities now consider dilatation with simultaneous division or incision of the constricting band the best, surest, and safest treatment of stricture. In cases where an instrument can be passed through the stricture, or where for other reasons the above method can not be resorted to, external urethrotomy is indicated. The operation is performed by cutting into the urethra from the perineum, thereby opening the stricture lengthwise. It is kept open by regular catheterization, so that the healing wound leaves a canal of normal size. Internal urethrotomy is only applicable in cases where at least a small instrument

can still be passed through the narrowed passage large enough to guide a small knife, which cuts and opens the stricture from inside. Revised by ROSWELL PARK.

Strigæ [Lat. *strix*, *strigis*, a kind of owl; possibly akin to Gr. *orpē*, a screeching bird]: an order or other group of birds embracing the owls. The eyes are directed forward, and are surrounded by a more or less completely formed facial disk of radiating feathers; the plumage is very soft and lax and the feathers are without an aftershaft; the toes are four, the outer reversible; the claws are long, sharp, and decurved; the external ear is very large, often with a movable flap. The bones inclosing the cerebral cavity have a spongy diploë; the maxillo-palatines are spongy, the latter separated by an interval wide throughout or reduced to a cleft below, and basipterygoid processes are developed. This group has been placed with the *Raptores*, but recent authorities remove it from this association and place it near the *Caprimulgidæ* or goat-suckers. See STRIGIDÆ.

Strigidae [Mod. Lat., named from *Strix*, the typical genus, from Lat. *strix*, *strigis*; possibly akin to Gr. *orpē*, a screeching bird]: a family of birds variously limited and defined. In the restricted and generally accepted sense, the *Strigidae* are owls having the breast-bone entire behind, with a central emargination, the furculum ankylosed, and the inner and middle toes of nearly equal length, the latter with its claw pectinate. It thus embraces the barn-owls, which are mostly of the Old World, though *Strix pratineola* is North American. The correlated *Bubonidae* have the sternum notched behind, the furculum free, the inner toe shorter than the middle, and the middle claw not pectinate. The feathers on the sides of the head are often elongated into ear-tufts in this family, which includes the common owls of the U. S. When the *Strigidae* are regarded as embracing all the species the groups above defined have sub-family rating. Revised by F. A. LUCAS.

Strike (in geology): See FAULTS.

Strikes and Lockouts: As defined by Carroll D. Wright, commissioner of labor for the U. S., a strike is the refusal of "the employees of an establishment to work unless the management complies with some demand." A lockout occurs when "the management refuses to allow employees to work except under some condition dictated by the management." Strikes and lockouts, therefore, are both warlike measures, and are declared to effect a specific object.

Antiquity of Strikes.—The first great strike of which we have record was that of the Hebrews in Egypt. There was a prolonged labor agitation, lasting many years, which the Egyptians endeavored to repress by imposing severer tasks upon the Hebrews. This was resisted, and many bloody encounters between serfs and masters occurred. Finally the labor forces were organized by Moses, with a general strike so thorough and well-arranged that the whole labor population marched out in a body and left their employers to their own devices. The employers were also said to be glad to get rid of their turbulent workmen. Ancient and mediæval history furnishes numerous examples of labor agitations of the nature of strikes, since inequalities of condition resulting from differences of ability in individuals keep a perpetual ferment in societies which issues in ill feeling and resentful strife between classes. Contention has characterized the history of all civilized nations, and where the industrial classes have been content to submit to unfavorable conditions the least advance has been made in civilization. The last half of the nineteenth century has seen the machinery and system of strikes brought to such perfection as to throw into the shade all previous movements of the same kind. The extension and generalization of trades-unions have led to such organization that strikes have become a recognized evil in social progress as much to be expected as changes of weather. They amount to a kind of inherent civil war.

Objects of Strikes.—A strike may be declared for one or more of the following objects: 1. To secure an advance or resist a reduction in wages. 2. To effect a reduction or oppose an increase of the hours of labor. 3. To resist the discharge of union men and hinder the employment of non-union men. 4. To regulate methods of work, materials used, number of apprentices, kind of work done by each branch of laborers, and the like. 5. To support a strike in some other industry or in some other branch of the same industry, as when pavers strike to help granite-cutters, or brakemen to help switchmen on a railway. These are known as sympathetic strikes. Strikes are wisely held by workmen to be

the last resort of a contest, and never to be risked until it is clear that the desired object can not be reached without them. They are expensive, arduous, and uncertain, and if rashly undertaken end in disaster after much suffering.

Boycotts.—To the earlier weapons of strikers, modern ingenuity has added the boycott, by which all markets are closed against the goods of the employer against whom a strike is ordered. Even his household business is interfered with, so that his grocer and butcher are forbidden to supply his necessities under pain of being cut off from most other customers. This has proved a very effective weapon in the hands of laborers.

Strikes in Great Britain.—Philip Bevan gives the number of strikes in Great Britain from 1870 to 1880 as 2,352, or 235 per annum. In 1888 they had risen to 504 for that year; in 1889, 3,164; in 1890, 1,028, involving 4,382 establishments. Strikes would seem, therefore, to be on the increase.

Strikes in the U. S.—The first recorded strike in the U. S. was that of the journeymen bakers in 1741. The leaders were tried for conspiracy. Next came the shoemakers of Philadelphia in 1796, 1798, and 1799; then the sailors in Philadelphia in 1803, who struck for \$14 against \$10 a month. They were arrested, and the leaders imprisoned. In 1809 the New York cordwainers struck, and used the term "scab" to denote non-strikers of their association. Printers struck in 1821, using the word "rat" for non-union men against whom they struck. In 1834 the first women's strike took place at Lynn, Mass., in the shoe-trade. It was unsuccessful. In 1848 the workmen of Allegheny city struck for ten hours, and carried their point after eight weeks of rioting, though with 16 per cent. reduction of wages. In 1850-51 1,300 workmen at Fall River were idle for six months at a loss of \$140,000 in wages. A strike at Pittsburg in 1850, marked by violence, resulted in sentences of fines and imprisonment to many, afterward pardoned. In 1852 mill-hands in Salisbury, Mass., struck for fifteen minutes' recess at lunch. In 1868 Pennsylvania passed a law making eight hours a legal day; much striking resulted among the coal-miners, resulting in less hours of work and more wages. In 1877 occurred the great railway strikes on the Baltimore and Ohio, the Pennsylvania, and the Erie systems, resulting in the destruction on July 21-23 of 1,600 cars, 126 locomotives, and \$5,000,000 worth of property, \$2,000,000 of which loss fell on the railways. In 1880 there were 762 strikes and lockouts together, 617 of which related to wages. Up to 1881 1,491 strikes and lockouts had taken place. Of these 1,089 were about wages, and 583 failed. From 1880 to 1890 there were 7,114 strikes, which involved 2,268,272 persons.

According to statistics of Carroll D. Wright, the strikes of 1882 affected 2,105 establishments; those of 1883, 2,759; 1884, 2,367; 1885, 2,284; 1886, 9,861. The average duration of strikes was twenty-three days. Loss in wages is estimated at \$51,814,723, and to employers over \$30,000,000; 1,323,208 employees were striking or involved, and 487,615 days were lost in all. Nearly four-fifths of these strikes were ordered by labor organizations. From 1881 to 1886 strikes affecting over 10,000 establishments succeeded, while strikes affecting about 9,000 failed. The trades represented were building, 6,075 establishments; tobacco, 2,959; mining, 2,060; clothing, 1,728; metallic goods, 1,570; transportation, 1,478. The lockouts were 2,214, of which 1,753 were ordered by organizations; 564 of these succeeded and 190 partially, and 1,339 failed. See *Third Annual Report of the Commissioner of Labor*, 1887.

In 1890 there were 798 strikes and 201,682 strikers. In the spring of 1892 occurred the granite-cutters' strike, which extended finally to pavers in New York, and arrested for a time the whole stone industry. This was, however, quite eclipsed by the famous strike in the Carnegie iron-works at Homestead, which was attended with such bloodshed and violence as to attract general attention. The Carnegie works were kept in a state of siege for several days, and the town presented the appearance of a military camp. Eight thousand soldiers were required to subdue the rioters, and though the strike apparently failed, yet it had a profound effect upon the industrial situation, and probably minimized the willingness of both laborers and capitalists to enter upon future battles. In the summer of 1894 a railway strike in Chicago and other Western cities, although a failure, threatened for a time the commercial interests of the whole country. It was ordered by E. V. Debs as president of the American Railway Union, in sympathy with striking employees of

the Pullman Car Company, and resulted in the calling out of U. S. troops to prevent the mails and feature order.

Expense of Strikes.—The cost of strikes is often figured out by statisticians, and runs into enormous sums—enough to make the laziest worker. Mr. Wright calculates that \$80,000,000 was lost in strikes and lockouts from 1881 to 1890. No doubt the funds of the unions—although now amounting to millions of dollars altogether—are often strained by the expenses of a great strike, and strikers and their families are subjected to extreme privations and distress before the contest is ended. Employers also are put to the greatest serious strain, and their business is often imperiled to the verge of bankruptcy. One lockout on the Clyde, in Scotland, was reckoned to have cost the unions \$750,000, while \$1,500,000 was lost in wages. A strike in Manchester, England, cost the unions \$400,000 and the employers \$1,500,000. These figures convey a sharp warning. They indicate what the strike in Chicago (1894) and the disastrous street-car strike in Brooklyn (1895) combine to teach—that strikes, like war, may easily cost more than they save in. It must be remembered, however, that, on the whole, strikes have seemed profitable to workmen; otherwise they must have ceased long ago.

Why Strikes are Induced Necessary.—Strikes result largely from men's ignorance of their true interests and well-being. False economic theories are responsible for a large part of the conflict between capital and labor, out of which strikes and lockouts are born. The false notion that profits must fall as wages rise—a notion contradicted flatly by history, which shows high wages and large profits inseparably yoked together—is partly responsible for the striking spirit. Really the antagonism of capital and labor is an inheritance from an ignorant past. It is also an inference of short-sighted reasoning which regards wages as surge and does not see that they immediately turn about and become income to the capitalists, since they are used to buy goods produced by labor, so that the higher the wages the larger the market becomes, and the greater the gross profits. On the other hand, also, the greater profits become the more capital stands ready to employ labor, and the stronger becomes the tendency in wages to rise in consequence. From the time when laborers were arrested and punished as conspirators, to the present day when they are regarded as disturbers of the peace and troublemakers of society, they and the upper classes have progressed together, often fighting but advancing most when co-operating rather than contending, and wages and profits have both risen greatly. The laborers get more wages, and their increased consumption increases the amount of goods needed, which enlarges the business of the capitalist and multiplies his profits. If this were not so, strikes would have ruined all parties long ago, impoverishing laborers and bankrupting capitalists.

Increasing Magnitude of Strikes.—The interests involved in strikes are constantly enlarging. The disturbances of 1892 at Homestead and New York and of 1894 and 1895 in Chicago and Brooklyn shivered the whole nation in its, as it were, engaged in these industrial convulsions, and that nothing but a scientific adjustment of the difficulties involved could bring about a condition of harmony and progress. A recognition of the economic principles involved alone will resolve the situation; and the main principle is the above law that wages and profits advance together, since profits are always largest in countries where wages are highest, and markets therefore largest. Lord Brassey, who has made a special investigation of the subject, has stated as a general truth that the higher-priced workmen are in reality the cheaper, on account of the quantity and quality of the work done. Low-priced labor is found to be dearest. Of course it would be but a visionary business policy to favor increasing wages were it not that wage advance means larger demand, increased consumption, and ultimately larger profits, out of which, again, further advances of wages may be made, as they will certainly be demanded by strikes.

Violence in Strikes.—The Buffalo switchmen's strike of Aug., 1892, called out 750 men, affected twelve railways, and lasted two weeks. There was some violence, and many cars were burned. It was declared hastily by Grandmaster McSweeney to secure ten instead of eleven hours' work, and 27 cents per hour instead of 25 cents. Night watchmen and soldiers were sent to Buffalo to put it down, and it failed, as strikes generally do unless carefully prepared. This appeared especially clear in the Chicago strike of 1894 and the Brooklyn strike of 1895. Violence nearly always endangers the strikers in public regard and defeats their

ends, while it supplies their resources. It is of no advantage to workmen striking for wages to destroy the property and of which wages come, and the impolicy of violence toward property is now becoming clear to strikers themselves; but toward workmen seeking to take the place of strikers there is still a very ready spirit of violence, which seriously threatens personal liberty and social order.

Success and Failure.—According to Carroll H. Wright's figures, about 50 per cent. of strikes succeed and about 50 per cent. of lockouts fail, as if the workmen were 50 per cent. wiser than the masters. This seems, however, to rather appear than real. As a matter of fact wages are seen to rise and fall from general causes just the same whether men strike or not.

Arbitration.—The great strike of the Shagwren Union in New South Wales in 1891, which finally involved so many industries, capitalists and workmen, skilled and unskilled, was made the subject of an elaborate examination by a parliamentary commission. The result was a recommendation of conciliation as a remedy, and if that failed arbitration without compulsory power. The same outcome resulted from a commission appointed to examine the Chicago strike and report. The idea is that such discussions and examinations as these measures necessitate tend to assuage ill feeling and promote reasonable conclusions sufficiently to carry force enough to settle disputes without other means. Doubtless there is truth in this position. Arbitration is also much valued as a means of preventing strikes and lockouts, by obviating the necessity for them. Doubtless as a temporary expedient it has value, as giving time for the adjustment of new disputes before they are definitely formulated; but arbitration is at best a broken reed to lean upon, inasmuch as the causes of strikes are now desires and new demands, which the rules of the past can not satisfy. The elements of the problem are usually whether a given business can afford to pay its employees more, or give them shorter hours or more privileges than they have been having. Evidently this is a question which only the employer can answer. He is the only one who knows, and therefore what a board of outsiders may say about the matter is liable to be totally irrelevant. If he can grant the laborers' demands, he will finally be willing to do it, because it is the more profitable alternative. If, however, he can not grant these demands, owing to the fact of an already depleted margin of profit, he will no more be able to do so because advised by a board of arbitration than without such advice.

SPENCER HOFF NICHOLS.

Strindberg. ANSWER: writer; b. in Stockholm, Sweden, Jan. 22, 1849. In 1870 he went to Paris, where he remained ten years. His first important works were the powerful dramas *Midas* (1879) and the social satire *Reda Brannan* (The Red Room), which was followed by dramas, novels, and tales, all displaying great originality and descriptive power. Among these may be mentioned *Ballets* (1881) (The Secret of the Club); *Mr. Berge's House* (Mr. Berg's Wife); *Erken Jule* (1886); and *Himmelstiehet Nycklar* (The Keys to the Kingdom of Heaven, 1892); and the novels *Lapska* (Lapska) (Utopias in Real Life, 1893) and *I Hattelandet* (In the Offing, 1891). Many of his works, especially the later ones, have aroused much controversy on account of the extreme social and moral views advanced in them. He is the leading apostle of naturalism in Sweden. D. K. DRUG.

Stringy Bark. See EUCALYPTUS.

Strobilation [= Gr. *στροβίλος*, anything twisted, pinwheel, etc.]: a process of reproduction occurring among certain jellyfishes (*Hydrozoans*), in which the larva becomes transversely divided into a series of disks (*Ephyrae*), each of which later develops into a medusa. The partially-divided larva was formerly regarded as an adult, and was called *Strobila*, in allusion to its appearance. A process akin to this occurs in the growth of the mushroom coral (*Fungia*) as well as in many tapeworms, in the latter resulting in the formation of the "pots" or proglottids. See TAPESOME. J. S. K.

Stroboscope [from Gr. *στροβίλος*, rotation + *σκοπεῖν*, to view]: an instrument for examining the motion of a body by intermittent sight. It was invented in 1822, independently, by Plateau in Belgium and Münster in Germany. In its simplest form it consists of a disk perforated near the circumference with a series of equidistant radial openings, through which the body is viewed while the disk rotates uniformly. Suppose, for example, that the body is vibrating, and that the time of one complete vibration is equal to that required for the disk to rotate through the angular

distance between two successive openings. The body will be seen in succession at the same phase of its motion, and will hence appear stationary. If the vibration period be slightly greater or less, the body will be seen successively in slightly different phases, and the visual impression is that of slow motion, the rate of which is calculable if the rate of rotation of the disk, the number of openings, and the period of the body be known. If the interval of time between the successive momentary views of the body be equal to or less than the duration of the retinal impression produced by it, the perception is uninterrupted. This duration decreases with increase of time of exposure of the retina and with increase in intensity of the light. The law determined experimentally by E. S. Ferry (see *American Journal of Science*, Sept., 1892, p. 204) is that retinal persistence varies inversely as the logarithm of the number which expresses the brightness. This means that if the intensity is increased by multiplying it by the second, third, or fourth power of some constant number, the corresponding duration will be one-half, one-third, or one-fourth of its original value. Under the conditions of ordinary daylight this duration varies from one-fiftieth to one-tenth of a second.

The principle of the stroboscope is applied in instruments to which a variety of names have been given, such as thaumatrope, phenakistoscope, vibroscope, zoetrope, zoopraxiscope, kinoscope, etc. If a succession of photographs of a rapidly moving body be taken at intervals of less than one-tenth of a second, and these be appropriately arranged for examination by the stroboscopic method, the resulting perception is that of the body in actual motion. With the development of instantaneous photography the preparation of such series of pictures has been brought to a high degree of perfection.

W. LE CONTE STEVENS.

Strombidæ [Mod. Lat., named from *Strombus*, the typical genus, from Lat. *strombus* = Gr. *στρόμβος*, a kind of spiral snail, also top, pine-cone, deriv. of *στρέφω*, twist]: a family of gasteropod molluscs. The shells vary considerably in superficial character, but all have a more or less conic spire, and in most the outer lip is expanded and deeply notched anteriorly. Species are generally diffused in all tropical seas, and between seventy and eighty are known. They are distinguished by the peculiar form of the foot, which is fitted for leaping rather than the crawling progression common to most gasteropods, and by the pedicles bearing the eyes and tentacles. They are quite active, but are reputed to be chiefly carrion-feeders. The shells are often employed as ornaments, and especially is this the case with the *Strombus gigas*, often known as the fountain-shell. This is the largest of the family, and sometimes weighs 4 or 5 pounds. It is also largely employed for the manufacture of cameos.

Revised by J. S. KINGSLEY.

Stromboli: northernmost of the Lipari islands, in the Mediterranean, off the north coast of Sicily; area, 8 sq. miles. It is wholly of volcanic formation, and has a constantly active volcano 3,040 feet high with an extinct crater on top, but an active one on the side at the height of about 2,150 feet. Cotton, wine, and fruit of superior quality are produced, and sulphur and pumice-stone are largely exported. On the east side lies the small town of Stromboli. Pop. of island, 500.

M. W. H.

Strong, AUGUSTUS HOPKINS, D. D., LL. D.: minister, educator, and author; b. at Rochester, N. Y., Aug. 3, 1836; graduated at Yale College 1857, and at Rochester Theological Seminary 1859; became Baptist pastor; pastor at Haverhill, Mass., 1861, Cleveland, O., 1865; president and Professor of Biblical Theology, Rochester Theological Seminary, 1872. He has published the following works: *Systematic Theology* (Rochester, 1886; 3d ed. New York, 1890); *Philosophy and Religion* (1888).

W. H. W.

Strong, GEORGE CROCKETT: soldier; b. at Stockbridge, Vt., Oct. 16, 1832; graduated at the U. S. Military Academy in July, 1857; assigned to the ordnance, and in 1861 took temporary command of the Watervliet arsenal, West Troy. He was ordnance officer on Gen. McDowell's staff at Bull Run, and was then attached successively to the staffs of Gen. McClellan and of Gen. Benjamin F. Butler, whose chief of staff he became. He aided in the organization of the expedition for the capture of New Orleans 1861; in Apr., 1862, commanded the successful expedition from Ship island to Biloxi, Miss., and in September that to Ponchatoula, which destroyed a large amount of property belonging to the Confederates. In Nov., 1862, he was appointed a brigadier-general of volunteers, and in June, 1863, assigned to command

of the brigade which, in the operations about Charleston, effected the landing on Morris island, July 10, 1863, Gen. Strong leading the successful assaulting column, as also the ineffectual assault on Fort Wagner the following morning. Again, a week later (July 18), his brigade led the second assault on that work, at the head of which Strong fell wounded. His commission as a major-general bore the date of the assault, July 18, and the name of Fort De Kalb, on the southern side of the Potomac, was changed to Fort Strong in his honor. D. of his wounds in New York, July 30, 1863.

Strong, JAMES, S. T. D., LL. D.: educator and author; b. in New York, Aug. 14, 1822; graduated at Wesleyan University in 1844; taught in Troy Conference Academy, Poultney, Vt., 1844-46; in 1847 removed to Flushing, Long Island; projected and built the Flushing Railroad, of which he was president; gave private lessons in Greek and Hebrew. In 1856, although not a clergyman, he received the degree of doctor of sacred theology from Wesleyan University, which institution also made him LL. D. in 1881; in 1858-61 was Professor of Biblical Literature and acting president of Troy University, and in 1868 became Professor of Exegetical Theology in Drew Theological Seminary at Madison, N. J. He was a member of the Anglo-American commission for the revision of the English version of the Bible. In 1873 he was chosen chairman of the archaeological council of the Oriental Topographical Society, and in 1874 made an extended tour in the East; prepared for Lange's *Commentary* the English translation of the part on the book of Daniel, and published *Harmony and Exposition of the Gospels*, in English (New York, 1852), *Harmony of the Gospels*, in Greek (1854), and brief manuals of the Gospels and of Greek and Hebrew grammar. About 1853 he projected, in association with Rev. John McClintock, D. D., a *Cyclopedia of Biblical, Theological, and Ecclesiastical Literature* (10 vols., 1867-81, 2 supplementary vols., 1884, 1887, with later addenda, bringing the work down to 1891). Dr. Strong taking the department of biblical literature, including sacred geography, antiquities, and natural history. On Dr. McClintock's death, Mar. 4, 1870, Dr. Strong assumed the supervision of the whole work. He also published *Irenica* (1896); *The Tabernacle of Israel* (1898); *Sacred Idyls* (1899); *Future Life* (1891); *Jewish Life* (1891); *Our Lord's Life* (1892); *Commentary on Ecclesiastes* (1893); and an exhaustive *Concordance of the Bible* (1894), on which he labored for more than thirty years. D. at Round Lake, N. Y., Aug. 7, 1894.

Revised by A. OSBOEN.

Strong, JOSIAH, D. D.: clergyman and author; b. at Naperville, O., Jan. 19, 1847; graduated at Western Reserve College, Hudson, O., 1869; studied theology at Lane Theological Seminary 1869-71. He was successively pastor of several Congregational churches (at Cheyenne, Wyo., 1871-73, at Hudson, O., 1873-76, at Sandusky, O., 1876-81); secretary of the Ohio Home Missionary Society 1881-84; pastor in Cincinnati 1884-86, when he became general agent of the Evangelical Alliance of the U. S. of America. He is the author of *Our Country* (1885, reissued in revised form 1891); *The New Era, or the Coming Kingdom* (1893).

G. P. F.

Strong, WILLIAM, LL. D.: jurist; b. at Somers, Conn., May 6, 1808; graduated at Yale College in 1828; was admitted to the bar in 1832, and commenced practice at Reading, Pa.; was representative in Congress 1849-54; in 1857 was elected a judge of the Supreme Court of Pennsylvania for fifteen years; resigned the position in 1868, and resumed practice at the bar, and in 1870 was appointed associate justice of the Supreme Court of the U. S. He retired 1880.

Strongylidæ [Mod. Lat., named from *Strongylus*, the typical genus, from Gr. *στρογγύλος*, round, spherical]: a family of parasitic round worms (nematodes) in which the mouth is usually surrounded by six papillæ or with a cup-like toothed expansion of these. Frequently in the male the end of the body has a bell-like expansion. Some species are parasitic in man, one, *Dochmius duodenalis*, causing the "tunnel disease" among the workers on the St. Gotthard tunnel, or "Egyptian chlorosis" in Africa, a disease occasionally fatal. Other species live in domestic animals, the "gapes" of fowl being caused by the presence of *Syngamus trachealis* in the windpipe.

J. S. KINGSLEY.

Strontium [Mod. Lat., deriv. of *Strontia*, from *Strontian*, in Argyleshire, Scotland, where strontia was first found]: the metallic basis of strontia, one of the alkaline earths, first obtained from native carbonate of strontium by Sir Humphry Davy in 1808. It is a pale yellow, burns with

a crimson flame, emitting sparks, decomposes water, liberating hydrogen gas; is hard, brittle, and fusible, and is obtained from the anhydrous chloride by electrolysis. Specific gravity, 3.64; atomic weight, 87.5; symbol, Sr. Its most important compound is the oxide called strontian, a grayish-white, porous mass, which combines with water to form a white powder, the hydrate of strontium (see HALL). This compound has acquired considerable importance in Germany for its use in extracting sugar from beetroot molasses. The sulfate SrSO_4 is much employed in the manufacture of the crimson lights in fireworks. The sulfates (SrSO_4) is a ferrous native, and is known as a crystalline mineral by the name of Celestine (q. v.). Revised by I. A. HARRIS.

Strophanthus: a genus of apocynaceous plants. From western African climbing shrubs of this genus is prepared a potent locally known as kumbo, mung, and mung, and used for the purposes of the chase and war. It has been shown by Prof. T. R. Fraser to contain a crystalline principle, strephanthin, which has a powerful influence upon the muscular system, first stimulating, but if in sufficient dose finally causing a general paralysis, ending in death through failure of the respiration. It affects not only the voluntary muscles but also the smooth fibers in the heart and in the walls of the blood-vessels; and since the first action, and indeed its entire action, when in minute doses, is stimulating, it has become a very valuable remedy in the treatment of failure of the heart from any cause. It resembles digitalis in its use in disease, but differs from that drug in being much more prompt and vigorous in its action, and in affecting more powerfully the kidneys. Though less powerful than digitalis, it may be often substituted with advantage for that drug, especially when promptness of action is required, or when it is necessary to rapidly relieve dropsical exaltations. The active principle, strephanthin, has been given in doses of 0.0002 to 0.0004 grammes, but the drug is chiefly used in the form of tincture, of which the dose is 3 to 10 drops. R. C. WOOL.

Strophe (via Lat. from Gr. *strophē*, a turning): unlike the Latin equivalent *versus*, a group of lyric poems, sometimes comprising several periods, combined into a symmetrical whole. In the Lesbian melic poetry it was a stanza usually of four lines, some of which were alike, which was repeated *ad libitum* with the same music. In the choric poetry of the drama and the lyric poets the role are more varied in form and usually more numerous, and the strophe was followed by another just like it, called the antistrophe, sung to the same music, the two being regarded as a complex unit, and the chorus executing a movement with the one and a counter-movement with the other, hence the names a "turning" and a "counter-turning." To this pair or evaggy was often (as always in Pindar) added another strophe without antistrophe, different in form, called epode (though, sung after, the three constituting the lyric "triad," see PAMPHY).

MURDOX W. HENDERSON.

Stroud: town, in Gloucestershire, England; on the Frome: 10 miles S. S. E. of Gloucester (see map of England, ref. 11-12). It is an important seat of woollen manufactures and dyeworks, the water of the Frome being well adapted for dyeing. Pop. (1891) 9,815.

Stroudsburg: borough; capital of Monroe co., Pa.: on Broadhead creek, in the Del., Lack. and West, and the N. Y., Susq. and West, railways; 4 miles N. W. of the Delaware Water Gap, 24 miles N. of Easton (for location, see map of Pennsylvania, ref. 4-1). It is in an agricultural region, has excellent water-power, and is surrounded by attractive scenery. It contains 2 national banks with combined capital of \$150,000, a building and loan association, hotel and hotel, and 3 weekly newspapers. Pop. (1880) 3,800; (1900) 2,419.

Struensee, JOHANN FRIEDRICH, Count of; minister to Christian VII. of Denmark; b. at Halle, Prussian Saxony, Aug. 5, 1757; studied medicine; and was appointed personal physician to Christian VII., over whom he gained a complete ascendancy. In 1771 he was made Minister of State, and a royal decree gave full authority to any orders he might issue, whether they were signed by the king or not. Struensee used his great influence to introduce sweeping reforms, some of which were beneficial to the people so tending to restrict the power of the nobles. Among other innovations he demanded the enfranchisement of the peasants, the introduction of examinations for public offices, the establishment of complete religious toleration and of liberty of the press.

The suddenness of these reforms and their radical nature aroused violent opposition, which culminated in a conspiracy against him. The story of an intrigue between him and the young queen Caroline Matilda was employed by the queen dowager to induce the king to order his arrest, and Christian, whose infatuated mind made him severely responsible for his actions, finally gave his consent. On Feb. 10, 1772, Struensee and the queen were arrested. No proof was advanced of his infatuation as a minister, but the threat of applying the tortures extorted from him a confession of guilty relations with the queen, and he was beheaded Apr. 28, 1772. See WEXELL, *Life and Times of Queen Caroline* (1804); JENSEN-JENSEN, *Die Verfassungsgeschichte des Königreichs Dänemark Matilda und die Herrschaft Struensee und Becholt* (1814); and WITTE, *Struensee* (1876). P. M. CARR.

Struggle for Existence: See RIVALRY.

Struma: See STOMACH.

Struppell, GEORGE AUGUST, M. D.; physician: b. at New-Amt. (Lüneburg), Russia, June 28, 1804; educated in part at the University of Dorpat, where his father was Professor of Philosophy, and at the University of Leipzig, where he graduated M. D. in 1830; from 1830-32 assistant at the Leipzig clinic; in 1832 appointed Extraordinary Professor of Internal Medicine at Leipzig University and director of the polytechnic; in 1836 appointed to the chair of Special Pathology and Therapeutics at the University of Erlangen. His most important work is *Lehrbuch der speziellen Pathologie und Therapie der inneren Krankheiten* (Leipzig), which has passed through seven editions and has been translated into French, Spanish, and English. A. T. AMMERSON.

Struthio: See SATONIA.

Struthionidae: an order of birds characterized by the structure of the palate, in which the vomer does not articulate with the pterygoids. The sternum is devoid of a keel. The group includes the South American *Struthio* (*Struthio*), *Struthio* (*Struthio*), *Struthio* (*Struthio*), and *Struthio* (*Struthio*). F. A. C.

Struthionidae (Mod. Lat., named from *Struthio*, the typical genus, from Lat. *struthio*, str., *repellere*, strike); a family of ratite birds. The bill is rather elongated, nearly straight, gradually depressed forward and narrowed toward the extremity, which is rounded, and the culmen is flattened; the nostrils are elongate-oval, and in a broad membranous groove near the middle of the bill; the feathers are destitute of after-shafts; the wings are imperfect, and furnished with long curving soft plumes; the tail is moderate, and consists of curved pendant feathers; the tars are elongated, robust, and mostly covered with hexagonal scales, but in front toward the toes with transverse ones, the toes are two in number, with pad-like under surfaces, the inner (third) large, the outer (fourth) small; the claws short, curved, and blunt.

A number of osteological characters support the differentiation of the family from the others of the group, and have been formulated by Prof. Huxley—viz., the maxilla palatinae are thickened at their inner edges, and articulate with facets upon the sides of the vomer; the vomer is quite short, and does not articulate with either the palatinae or pterygoids behind; the prefrontal processes of the premaxilla are deficient in ossification; the sacral vertebrae are united by their bodies with the anterior ends of the pubes and ischia; the sternum has two shallow notches on each side at the posterior margin; the manus possesses the ordinary three digits, and of these the radial and middle have claws; there is a union of the pulvis in a symphysis; the hallux is not only adjoined, but also the distal end of the metatarsal bone and the phalanges of the second digit of the foot. See OXYGEN.

Revised by F. A. LAYMAN.

Strott, JOHN WILLIAM, third Baron Rayleigh, F. R. S.; physicist; b. in England, Nov. 12, 1818. He was educated at Cambridge, and graduated 1840; became fellow of Trinity College 1846; succeeded to the title 1873; Professor of Experimental Physics in the University of Cambridge 1878-84; and Professor of Natural Philosophy in the Royal Institution of London since 1867. He is a member of numerous scientific societies and a correspondent of the Institute of France. He is the author of several memoirs relating to acoustics and electricity in the *Philosophical Transactions of the Royal Society*, of numerous papers in scientific journals, and of *The Theory of Sound* (2 vols., 1877-78; 2d ed., 1894). In 1894, in conjunction with Prof. Ramsay, he discovered, and has since prepared in quantity, a new element in the atmosphere, which he has called argon. For this discovery the trustees

of Columbia College, New York, on the recommendation of the National Academy of Sciences, awarded Lord Rayleigh in 1895 "the Barnard medal for meritorious service to science." The discovery originated from the fact that the supposed nitrogen of the atmosphere was always found to be heavier than the nitrogen obtained by chemical means—from ammonia, for instance—the explanation being given by the admixture of the heavier gas, argon, with the former. The atomic weight of argon is 19.9, as compared with 14 of nitrogen, if it is assumed to be a single element. It would thus come between fluorine and sodium in the series of elements. It is believed that the gas was obtained in 1892 from the mineral uraninite by the American chemist W. F. Hillebrand, who by not applying sufficient tests concluded that it was nitrogen. Argon has since (1895) been found by Ramsay in the Norwegian mineral cleveite in conjunction with the solar element helium. (See SPECTRUM.) It differs in a remarkable way from all other known elements in its inertness or absence of chemical properties, whence its name (Gr. ἀργόν, neut. of ἀργός, lazy). Lord Rayleigh, however, believes that it has some affinity with certain of the hydrocarbons, and Prof. Berthelot, of Paris, has induced it to combine with the vapor of benzene, the product formed being a yellow resinous substance. In the course of his experiments in passing electric currents through argon mixed with benzene, Berthelot has obtained splendid displays of colors similar to those of the aurora borealis, which phenomenon, it is thus suggested, may be due to the action of electric currents upon the argon in the atmosphere. Its spectra have been studied by Crookes; they are of two kinds, with bright lines conveniently named red and blue, which are obtained under different conditions of pressure and electric current. The gas has been liquefied and solidified by Olszewski of Cracow. It dissolves in water under the ordinary pressure at 14° C. in the proportion of 4 volumes to 100, and is thus about three times as soluble as nitrogen. The critical temperature under 50 atmospheres is — 121. The density of liquid argon at its boiling-point is about 1.5.

R. A. ROBERTS.

Strutt, JOSEPH: antiquary: b. at Springfield, Essex, England, Oct. 27, 1742; was apprenticed to an engraver, but early devoted himself specially to the study of British antiquities. His principal works in this department are *The Regal and Ecclesiastical Antiquities of England* (1773; new ed. by Planché, 1842); *Horde-Angel-Cynnan*, being a view of the customs, arms, etc., of the inhabitants of England from the arrival of the Saxons till the reign of Henry VIII. (1774-76); *The Chronicle of England*, completed only to the time of the Norman Conquest (1777-78); *Complete View of the Dress and Habits of the People of England from the Establishment of the Saxons to the Present Time* (1796-99; new ed. 1875); *The Sports and Pastimes of the People of England* (1801; often republished). He also published a *Biographical Dictionary of Engravers* (1785-86), and left several tales, one of which, *Queen Hoo Hall*, was edited after his death by Sir Walter Scott. D. in London, Oct. 16, 1802.

Struve, stroo've, FRIEDRICH GEORG WILHELM, von: astronomer; b. at Altona, Holstein, Apr. 15, 1793; studied first philology, and afterward astronomy, at the University of Dorpat; received an appointment at the observatory in 1813, and became its director in 1817. From 1834 to 1839 he planned and superintended the construction and erection of the observatory at Pulkowa, near St. Petersburg, which he has described in his *Description de l'Observatoire central de la Russie* (1845), and of which he was director to his death Nov. 23, 1864. This observatory became the most noted of the world. The earlier part of his career was mostly occupied by studies of double stars and of the construction of the Milky Way—*Observationes Dorpatenses* (8 vols., 1817-39); *Catalogus novus stellarum duplicium* (1827); *Stellarum duplicium mensura micrometrica* (1837); *Stellarum fixarum, imprimis compositarum, positiones medie* (1852); and *Études d'astronomie stellaire* (1847). Subsequently he undertook several great geodetic works, such as the triangulation of Livonia (1816-19) and the measurement of a meridian arc in the Baltic provinces (1822-27), which he continued to the North Pole in connection with Hansteen, and to the Danube in connection with Gen. Tenner, and which he has described in his *Arc du méridien entre la Danube et la Mer Glaciale* (1861).

Revised by S. NEWCOMB.

Struve, GEORG ADAM: jurist; b. at Magdeburg, in what is now Saxony in Prussia, Dec. 27, 1619; studied law at

Jena and Helmstedt; held the offices of court assessor, private counselor to the Duke of Weimar, and Professor of Law in the University at Jena; and in 1680 was appointed president of the regency of Weimar, the then duke being a minor. Of his numerous elaborate legal treatises the most important are *Syntagma Juris Feudalis* (1653); *Syntagma Jurisprudentiæ Civilis* (1655); and *Jurisprudentia Romano-Germanica Forensis* (1670). D. at Weimar, Sept. 15, 1692.—His son, BURKHARD GOTTHELF STRUVE (b. at Weimar, May 26, 1671; d. at Jena, May 24, 1738), was a jurist and historian. He studied law, traveled, was appointed librarian of the University of Jena 1697, then Professor of History 1704 and of Jurisprudence 1730. He was historiographer to the house of Saxony. The most important of his many works are *Syntagma Historiæ Germanicæ* (1716); *Corpus Juris Gentium*; *Publici* (1717); and *Bibliotheca Historica* (11 vols., 1705).

F. STURGES ALLEN.

Struve, OTTO WILHELM, von: astronomer; b. at Dorpat, Russia, May 7, 1819; son of Friedrich Georg Wilhelm von Struve, under whom he studied astronomy; succeeded him as director of the observatory of Pulkowa, and became known in the history of astronomy by many valuable researches. His *Determination of the Constant of Precession* is a classic, as is also his *Measurements of Double Stars*, a continuation of his father's work. He visited the U. S. in 1879 to order the object-glass of the proposed great telescope of his observatory from A. Clark & Sons, and again in 1883 to receive the glass. He resigned the directorship at Pulkowa in 1890.

SIMON NEWCOMB.

Strychnine, or Strychnia: See NUX VOMICA.

Strychnos [Mod. Lat., from Gr. στρίχνος, a kind of nightshade]: a genus of trees and climbing woody vines of the family *Loganiaceæ*, found in the tropical parts of Asia and America. Most species are poisonous. *S. nuxvomica* of India (see NUX VOMICA), a tree of moderate size, yields the alkaloids strychnine, brucine, and igasurine, all active poisons in overdoses. Equally poisonous are the *S. ignatica* of the Philippines and *S. tieute*, a climbing vine of Java. The East Indian *S. ligustrina* and *S. colubrina* are reputed to cure snake-bites. *S. pseudo-quina* of Brazil yields copalche-bark, a valued febrifuge; *S. potatorum* of India is the clearing-nut tree; and *S. toxicaria* of South America probably affords the dreaded curare (or woorari) poison.

Revised by L. H. BAILEY.

Stryker, MELANCTHON WOOLSEY, D. D., LL. D.: clergyman and educator; b. at Vernon, N. Y., Jan. 7, 1851; educated at Hamilton College and Auburn Theological Seminary; pastor of Calvary church, Auburn, N. Y., 1876-78; First Presbyterian church, Ithaca, N. Y., 1878-83; Congregational church, Holyoke, Mass., 1883-85; Fourth Presbyterian church, Chicago, 1885-92; since 1892 president of Hamilton College. He has published *The Alleluia* (1884); *Church Praise Book* (New York and Chicago, 1881); *Christian Chorals* (1885); *Church Song* (1890); *Choral Song* (1891); *Miriam and other Verse* (1888); *Essay on Des Ire* (1892); and *Inaugural Address, Hamilton College* (1893).

C. K. HOYT.

Strype, JOHN, D. D.: ecclesiastical historian; b. at Stepney, England, Nov. 1, 1643; educated at St. Paul's School and at Cambridge; from about 1670 to about 1732 held the living of Low Leyton in Essex; later was settled at Tarring, Sussex. His important works are *Annals of the Reformation in England* (4 vols., 1709-31); lives of *Thomas Cranmer* (1694), *Sir Thomas Smith* (1698), *John Aylmer* (1701), *Sir John Cheke* (1705), *Edmund Grindall* (1710), *Matthew Parker* (1711), and *John Whitgift* (1718); and *Ecclesiastical Memorials* (3 vols., 1721). Editions of the *Historical and Biographical Works of John Strype* were issued from the Oxford Press in 27 vols. (1827-40). D. at Hackney, Dec. 11, 1737.

Stuart: town; Guthrie and Adair cos., Ia.; on the Chi. Rock Is. and Pac. Railway; 41 miles W. of Des Moines, 165 miles E. of Omaha (for location, see map of Iowa, ref. 5-F). It is on a high rolling prairie, and contains 6 churches, 4 public-school buildings, electric lights, large locomotive and machine shops, a national bank with capital of \$75,000, a State bank with capital of \$50,000, and 2 weekly newspapers. Pop. (1880) 1,994; (1890) 2,052; (1895) estimated, 2,500.

EDITOR OF "LOCOMOTIVE."

Stuart, or Stewart: a royal family which has given several sovereigns to Scotland and England. They trace their descent to a Norman baron, Alan, who accompanied William

the Conqueror, and received large gifts of land in England. His second son went to Scotland, entered the service of King David I. (about 1180), by whom he was made steward of the kingdom, the dignity remaining hereditary in the family, who assumed the title as their family name. The sixth of these stewards or Stewarts married in 1313 a daughter of Robert Bruce, and their son Robert in 1329 succeeded David Bruce on the throne of Scotland, under the title of Robert II. The following are the sovereigns of the Stuart line, with the dates of their accession: ROBERT II. (1329); ROBERT III. (1390); JAMES I. (1424); JAMES II. (1437); JAMES III. (1460); JAMES IV. (1488); JAMES V. (1503); MARY, Queen of Scots (1542); JAMES VI, crowned King of Scotland in 1568, King of England under the title of JAMES I. (1603), and transmitted both thrones to his successors: CHARLES I. (1625); CHARLES II. (1649); and JAMES II. (1685). For an account of the reigns of these monarchs, see the respective titles. JAMES II.'s son, JAMES EDWARD FRANKS STUART (q. v.), assumed the title of JAMES III. upon the death of his father, and is known in history as the Old Pretender. His eldest son, CHARLES EDWARD (q. v.), is known as the Young Pretender. Henry, the second son of the Old Pretender (see STUART, HENRY BENEDICT MARIA CLEMENT), died in 1807, and with him ceased the line of the Stuarts. The present royal family of England are descended only indirectly, and in the female line, from the Stuarts, through a granddaughter of James I. of England, upon whom the succession was bestowed by Parliament. R. M. COLAR.

STUART, ANNE (A.): member of the royal house of England and Scotland; b. at Chatsworth about 1575. Her father was Charles Stuart, Earl of Lennox, brother of Lord Darnley. She was in the direct line of descent to the English crown, standing in the same degree of relationship to Elizabeth as did her cousin James, and she became a subject of frequent intrigues. Upon the death of Elizabeth in 1603, an unsuccessful plot, in which it is said Sir Walter Raleigh was implicated, was formed to place her instead of James upon the throne; and from this moment she became an object of jealousy to her cousin; this was still more inflamed when in 1610 she was secretly married to William Seymour, grandson of the Earl of Hertford, who was also in the line of descent. Seymour was thrown into the Tower, and his wife was placed in the custody of the Bishop of Durham. She managed to escape, and made her way to the coast, where a French vessel was waiting for her and her husband, who had escaped from the Tower. He did not succeed in reaching the vessel, which sailed without him, but found another one, by which he reached France. The vessel in which was the Lady Arabella was captured by an English ship, and she was imprisoned in the Tower, where she became insane, and died Sept. 27, 1615. R. M. COLAR.

STUART, GILBERT CHARLES: painter; b. at Narragansett, R. I., Dec. 9, 1753. His first instructor, Alexander, a Scotch artist, took him to Edinburgh in 1775, and soon died, but the youth worked his way back to Newport. Thence he removed to Boston. The stir of the Revolution drove him to New York, and thence in 1789 to London. There, after months of poverty, friendlessness, and illness, he became acquainted with Benjamin West, who gave him encouragement and showed him every kindness. A full-length portrait of West, now in the National Gallery, gained for him reputation and opportunity. He soon rose to eminence in London, and painted people of rank—George III., the Prince of Wales, John Keble, Joshua Reynolds (of whom he was held to be the peer). The Duke of Rutland invited him to Dublin, and there he lived in splendor as the artist of the nobility. In Paris he met with similar fortune, having as a sitter the king, Louis XVI. A desire to revisit his native country and to paint the portrait of Washington, whom he profoundly revered, led him to return to the U. S. in 1793. The first picture of the President was destroyed as unsatisfactory; the second, the original sketch whereof is in the Boston Athenaeum, is the accepted portrait. Besides Washington, Stuart painted John Adams, Jefferson, Madison, Monroe, John Jay, and many other distinguished men and women of the day. The last painting was that of John Quincy Adams, which was finished by Sally. From 1806 till his death Stuart resided in Boston, and painted industriously. D. in Boston, Mass., July, 1828. No complete catalogue of his portraits exists. They are more than 150 in number, and are greatly prized. In the painting of heads he rivaled Cop- ley, but the details are sketchy. Stuart was a brilliant man, sensitive, sensitive, proud, a wonderful talker, a penetrating

observer, a genius in his art. In his early years he was an accomplished musician. His pictures are widely scattered, and are mostly in private hands.

STUART, HENRY BENEDICT MARIA CLEMENT: last male descendant of the royal house of Stuart in the direct line; b. in Rome, Mar. 3, 1723; the son of the Pretender, James Francis Edward Stuart, by whom he was created Duke of York. He was preparing to join his brother in the rising of 1745 with a force of French troops when that prince was overthrown at Culloden, subsequently took orders in the Roman Catholic Church, and in 1747 was raised to the cardinalship by Pope Benedict XIV. as Cardinal York, taken from his dual title. In 1766, on the death of his brother, the Young Pretender, he assumed the style of Henry IX., King of England—*pretitio Dei, non voluntas hominum*, as expressed on a medal struck upon the occasion. When the French troops in 1793 took possession of the papal states he retired to Venice, but returned in 1801. During the later years of his life he was maintained by a pension from the British Government. D. at Frascati, July 12, 1807.

STUART, JAMES: archaeologist and architect; b. in London in 1712, until nearly thirty years of age was a dandy of fashions and similar articles; made his way to Rome, where he studied Greek and Latin art and archaeology; in 1752 accompanied the antiquarian Nicholas Revett to Athens, where he remained three years, making drawings from the remains of Greek architecture; in 1755 returned to London; became eminent as an architect; was appointed surveyor of Greenwich Hospital, and in conjunction with Revett began the great work, *The Antiquities of Athens, Measured and Illustrated* (3 vols., 1762-94); supplementary volume, edited by Joseph Woods, 1816. This work may be said to have first made clear to Europe that there existed a Grecian architecture very different from the Greco-Roman of Italian and French ruins. A second supplementary volume was published in 1830 by Messrs. Cockrell, Kimball, Donaldson, Jenkins, and Balton. He also published *Cyclical Observations on the Buildings and Improvements of London* (1771), and furnished the illustrations for a *Naturalist's Tour through part of Europe, Asia, and Africa* (1783). D. Feb. 2, 1795. Revised by ROBERT STUART.

STUART, JAMES EWELL BAUM: soldier; b. in Patrick co., Va., Feb. 6, 1856; graduated at the U. S. Military Academy July 1, 1884, when appointed a brevet second lieutenant in the regiment of mounted rifles, receiving his full commission in October. In Mar., 1885, he was transferred to the newly organized First Cavalry, in which regiment he attained a first lieutenancy in the following December, and a captaincy Apr. 22, 1891. During the Kansas political troubles of 1885-88 he served with his regiment, and in 1889 was a volunteer aide to Col. Robert K. Lee during the John Brown insurrection at Harper's Ferry. On May 10, 1891, he was appointed lieutenant-colonel and July 16 colonel of a Virginia cavalry regiment, and was in chief command of the Confederate cavalry at the first battle of Bull Run. Promoted to be brigadier-general in the Confederate army in Sept., 1861, and major-general in July, 1862, he served thenceforth with the Army of Northern Virginia. Gen. Lee, assuming command of this army (June, 1862), and having reorganized it, determined upon a bold maneuver prior to resuming the offensive. Accordingly, on the morning of June 12, Stuart, with some 1,500 cavalry and four guns, left Richmond, and on the morning of the 18th reached Hanover Court-house, where he met and drove back two squadrons of the Fifth U. S. Cavalry; proceeding down the Pamunkey as far as Old Church, thence toward New Kent Court-house, striking the railway at Tonsill's Station, and crossing the Chickahominy at Jones's Bridge the next morning, was safely back in Richmond that night, having made the circuit of McClellan's army with the loss of but one man. This cavalry raid, the first use of the war, caused much commotion in the Union army, and was the source of valuable information in the subsequent movements of Jackson, where Stuart led the advance. During Pope's campaign in Northern Virginia, Stuart surprised the headquarters train of the former near Catlett's Station on the night of Aug. 22, 1862, capturing the personal baggage and official correspondence of Pope, and on the night of the 26th and morning of the 27th, in connection with two regiments of infantry, made a descent on Manassas Junction, capturing eight guns, several hundred prisoners, ten locomotives, and immense quantities of quartermaster and commissary stores. During the invasion of Maryland by Gen.

Lee in September, Stuart covered the Confederate rear, resisting the Union cavalry advance at South Mountain and holding the Confederate left at Antietam. During the subsequent period of inaction he crossed the Potomac above Williamsport with 1,500 cavalry Oct. 9, 1862, and passing through Maryland, he entered Pennsylvania and occupied Chambersburg on the 10th, and recrossed the Potomac below Harper's Ferry Oct. 12. In the battle of Fredericksburg his command formed the extreme right of the Confederate line. At Chancellorsville, after the fall of Stonewall Jackson and the disablement of Ambrose P. Hill, Stuart succeeded to the temporary command of Jackson's corps, which he led with ability in the severe fighting of Sunday, May 8. In anticipation of the proposed invasion of Pennsylvania, a large cavalry force had been accumulated at Culpeper under command of Stuart, against which Gen. Hooker dispatched two divisions of cavalry and two brigades of infantry, which, crossing at Beverley and Kelly's Fords (June 9), soon encountered Stuart advancing to cover the flank of the main movement. A fiercely fought but indecisive battle between the cavalry on both sides ensued, resulting in a loss to each of 500 or 600. During the subsequent campaign of Gettysburg he passed up through Eastern Maryland and Pennsylvania, and rejoined Lee at Gettysburg. In the campaign of 1864, Stuart by a wide detour succeeded in interposing himself between the Confederate capital and Sheridan's advancing column. Concentrating all his forces at Yellow Tavern, near Richmond, he was here attacked by his able rival. During the obstinate but ineffectual struggle Gen. Stuart was mortally wounded. D. May 12, 1864, soon after reaching Richmond. See *The Campaigns of Stuart's Cavalry*, by H. B. McClellan (Boston, 1885).

Revised by JAMES MERCUR.

Stuart, JAMES FRANCIS EDWARD: See JAMES FRANCIS EDWARD STUART.

Stuart, JOHN, Earl of Bute: See BUTE.

Stuart, MOSES: biblical scholar and educator; b. at Wilton, Conn., Mar. 26, 1780; graduated at Yale College 1799; studied law, and was admitted to the bar in 1802, and for two years was tutor in Yale College; afterward studied theology with President Dwight, and in 1806 was ordained pastor of the First church (Congregational) in New Haven. In 1809 he became Professor of Sacred Literature in the Theological Seminary at Andover, Mass., and occupied the chair until 1848. By his stimulating influence as a teacher and author, he made an epoch in the study of biblical literature in the U. S. He was the teacher of more than 1,500 ministers. He held his professorship for thirty-eight years. He published several Hebrew and Greek grammars, commentaries on various books of the Bible, of which his works on the epistles to the Romans and the Hebrews are among the most prominent, and *Elements of Interpretation* from the Latin of Ernesti (1822); *The Sabellian and Athanasian Modes of Representing the Doctrine of the Trinity*, from the German of Schleiermacher (1835); *Philological View of Modern Doctrines of Geology* (1836); *Hints on the Prophecies* (1842); *Critical History and Defense of the Old Testament Canon* (1845); *Conscience and the Constitution* (Boston, 1850); and other works. D. at Andover, Mass., Jan. 4, 1852.

Revised by G. P. FISHER.

Stub, stoob, AMBROSIVS: poet; b. on the island of Fünen, Denmark, May, 1705. The greater part of his life was spent in poverty, his genius failing to win recognition till long after his death. After serving as private tutor at various estates he finally established a private school in Ribe, where he spent the latter part of his life. He was the only great lyric poet of his time, and may be regarded as a worthy predecessor of Ewald and Wessel. All but one of his poems were published posthumously (1771). He is the original of the hero of C. K. F. Molbech's romantic drama *Ambrosius*. D. at Ribe, July 15, 1758. His collected poems were edited by Fr. Barfod (Copenhagen, 5th ed. 1879).

D. K. DODGE.

Stubbs, WILLIAM, D. D., Bishop of Oxford: historian; b. at Knaresborough, England, June 21, 1825; was educated at the grammar school at Ripon and at Christ Church, Oxford, where he took a first class in the classics and a third class in mathematics, and was elected to a fellowship in Trinity College; took holy orders in 1848; became vicar of Navestock in 1852; librarian to the Archbishop of Canterbury at Lambeth in 1862, and was school inspector in the diocese of Rochester 1860-66, when he received the appointment of Regius Professor of Modern History at Oxford.

In 1869 he became curator of the Bodleian Library; was chosen as a member of the hebdomadal council in 1872, and in 1875 received the presentation of the rectory of Cholderton, Wiltshire. He was appointed canon residentiary of St. Paul's in 1879, consecrated Bishop of Chester in 1884, and became Bishop of Oxford in 1889. He has published *Hymnale secundum Usum Sarum* (1850); *Registrum Sacrum Anglicanum* (1858); *The Foundation of Waltham Abbey* (1861); *Chronicles and Memorials of Richard I.* (1864); the *Chronicle of Roger de Hoveden* (1868); *Select Charters, etc., of English Constitutional History* (1870); *Memorial of Walter of Coventry* (1872); *Memorials of St. Dunstan* (1874); *The Constitutional History of England* 3 vols., 1874, 1875, and 1878; and (with Haddam) *Councils and Ecclesiastical Documents relating to Great Britain and Ireland* (1869-78). His *Constitutional History of England* is one of the ablest and most authoritative works on the period of which it treats.

F. M. COLBY.

Stucco [= Ital.: Fr. *stuc*, from O. H. Germ. *stucchi*, piece > Mod. Germ. *stück*]: plastic, adhesive composition applied to walls both internally and externally in order to give them a smooth and even surface, either decorative or plain in color or form. The cementing medium of the composition for inside work is common lime or calcined gypsum, or a combination of the two, generally mixed with a certain proportion of sand, depending on the special object to be secured. The word *stucco* technically applies to a mixture of lime-pulver and white sand or powdered marble, and to a coating produced with this compound. The rudest example of the plasterer's art is the application of a single coat of mortar composed of lime-paste and common sand laid on the surface of a wall with the trowel, while the highest consists in imitating fine marbles and other beautiful building-stones by using pure calcined gypsum, mixed with gum, isinglass, and suitable coloring-matter, laid on in a variety of decorative forms in order to produce panels, pilasters, mouldings, cornices, etc. The implements used by the plasterer are of the simplest kind and few in number. They comprise a lathing-hammer, the hawk, the plastering or laying-on trowel, the float, a brush, and straight-edges and moulds of various kinds, together with a screen, shovel, rake, and bud for his attending laborer. The hawk is used by the plasterer for holding the mortar in his left hand while he applies it with the trowel held in his right hand. It is simply a piece of board about 10 to 11 inches square, held by a stout handle fixed on the under side in the center of the board and at right angles to it. The laying-on trowel is a thin plate of hardened steel or iron about 3 inches wide and 9 to 10 inches long, rounded slightly at the front end, square at the other end, and a little convex on the face. It is provided with a handle on the back parallel to the blade. The hand-float is of wood, shaped something like the laying-on trowel. It is used to rub down finished work and give it a hard, smooth, and even face. A cork float is sometimes used upon surfaces which are to receive a high degree of polish. A derby is a long, two-handed float, used principally in forming the floated coat of lime and hair. Jointing-trowels are of steel, the plate being triangular, with an acute angle at the front end, the handle being attached to the heel or base of the tool. They are used about cornices and mouldings in forming the miters where fine workmanship is desired. A corner-trowel is like a small laying-on trowel with its face bent lengthwise to a right angle; it is used at the intersections of walls and ceiling, etc. Moulds are pieces of hard wood cut to the form of the cornices or mouldings that are to be formed, to assist the workman in securing accuracy and uniformity in his work. They are sometimes made of copper plates inserted in a wooden stock. The plasterer's brush is broad and thin, and is used for keeping the material wet and plastic until it is finished to the required form. The plasterer's materials are lath-nails, laths, lime, calcined gypsum or plaster, hydraulic cement, and sand, together with various pigments for giving the requisite colors.

The mortars used for inside plastering are "coarse stuff," "fine stuff," "gauge stuff," called also "hard finish," and "bastard stucco." Coarse stuff is simply common lime-mortar, of the quality suitable for brick masonry, mixed with well-switched bullock's hair free from all animal and vegetable matter. Fine stuff is prepared by slaking pure lump-lime with a small quantity of water, and afterward adding water until the paste is diluted to the consistency of cream. It is then allowed to stiffen by evaporation to the proper

composition for use. It is then sometimes called putty. It is used for the finishing coat, but always with some fine sand or sifted plaster, except for what is known as a slipped coat, and even for slipped work fine sand may be added in small quantities. Franco stuff is composed of putty or fine sand and strained gypsum, in the proportion of 3 or 4 of the former to 1 of the latter. The mixture called stucco is prepared with lime-putty and white sand, and is used only for a finishing coat.

After coat of plastering on laths is said to be *laid*, and the coat is called a *laying-coat*; and work in two coats is said to be *laid and set*, and the mortar is styled a *laying coat* and a *set coat*. In three-coat work on laths the first is called the *prepared* coat, the *scratch* coat, the second is the *float* coat, and the third the *set* coat. In masonry, plastering in one coat is styled *rendering*; two-coat work is said to be *rendered and set*; and three-coat work *rendered, floated, and set*. In good two-coat work upon laths, and also upon masonry, the first coat should be a *scratch coat*—that is, laid in screeds and "filling out." The screeds are strips or bands of coarse stuff, 6 or 8 inches in width, applied at the angles of the room, and also in parallel strips 3 or 4 feet apart all over the walls and ceiling. They are carefully worked out, so that all those on the same wall or ceiling shall be accurately in the same plane, as determined by the frequent application of the straight-edge in all possible directions. When the screeds have become somewhat firm, the spaces between are filled in flush with the surfaces already established, so as to produce a continuous straight and even surface. In three-coat work the second is the *scratch coat*. One-coat work on either laths or masonry—that is, either *laid or rendered*—although an inferior quality of work for walls and ceilings, is in common use for attics, kitchens, cellars, vaults, and places of like character. After the first coat of two-coat work has become partially dry, so that it will not break up under the trowel in the work which follows, it is in readiness for the coat or finishing coat, which may be in *slipped work, stucco, sand and siccato, or hard finish*.

Hard finish is applied with a trowel to the depth of an eighth of an inch, and may be polished with the water-lime and trowel, but not hand-floated. Hard finish requires the best labor, and is extensively practiced in the U. S. In three-coat work on laths, the first coat—the *prepared* coat, the *scratch*, or *brown coat*—is applied in the same way as *laying*, with the exception that inasmuch as it is designed to form merely a good foundation for the *scratch coat*, its thickness does not usually exceed one-quarter to three-eighths of an inch. After it has become partially dry, but while still soft, the mortar is *scratched* over nearly to its entire depth with a stick cut on the end into pointed teeth. The scratching is done in two sets of parallel strokes at right angles to each other, each running diagonally across the surface. The lines are about 2 inches apart, and are designed to assist the adhesion of the *scratch coat* which follows. The second and finishing coats are applied as already described for a *scratch coat* and *set*.

For exterior plastering a mortar composed of common lime and sand is not the most suitable, although frequently used upon the walls of common buildings well protected by projecting eaves. A cheap and useful surfacing of this kind is made by first cleaning off and roughing up the surface and making out the joints to the depth of half an inch, and then rendering it with a not very thick coat of lime-paste and hair. When this has set, another coat of the same mixture is laid on evenly with the trowel without floating; and as soon as a few square yards are executed a semi-fluid and thoroughly incorporated mixture of strong lime and fine clean gravel is freely applied. This is at once, while soft, troweled to any desired color with an ochreous mixture put on with a brush. The whole dries and hardens into a compact mass.

Common lime forms the basis of some very good outside stuccoes, which, when properly applied, are very durable. Water holding coarse brown sugar or molasses in solution may be used for mixing the mortar, with beneficial effects on subsequent induration. One lb. of sugar to 5 gal. of water will answer for all except the surface coat, which should contain four times this proportion of sugar. Powdered slaked lime, mixed with the scales from a smith's forge and tempered with bullock's blood, produces a moderately hydraulic and durable mortar, frequently used for exterior stuccoes. The wall should be previously coated over with melted oil. In the U. S. hydraulic cement and clean, sharp sand, mixed up with fresh water to the consistency of plasterer's mortar, is now commonly used for the exterior

rendering of walls, more especially of brick walls. The mortar is usually applied in two coats in one operation; that is, the second coat is put on while the first is yet soft and plastic, so that the two become one. The workman never scores more than 2 or 3 superficial feet at one time, finishing it off with the second coat as he goes along. The aggregate thickness of both coats should be about half an inch. It should be protected from the direct rays of the sun for some days, and kept moist by sprinkling with a hose or brush. Sometimes the first coat is replaced by a wash of thin cream of pure cement, put on while a brush just in advance of the mortar. Faithful workmanship is most essential in this kind of plastering. The mortar must be put on under a firm pressure with the trowel, in order to secure intimate contact with the wall, and the surface must not be too dry. Deficient adhesion will result from neglect of these precautions. When a cement is too dark to give an agreeable shade of color, a judicious use of white sand, common lime, and ochre, singly or in combination, may generally be depended upon to greatly lessen if not entirely remove the objection.

Certain precautions are indispensable to the durability of stucco upon the exterior faces of walls. In the first place, the sand used must be perfectly clean, and should therefore be washed, repeatedly if necessary, until it will no longer discolor clean water. The most destructive agent to be guarded against is frost, when accompanied by the penetration of moisture between the stucco and the wall, which will inevitably result in throwing off the mortar. In well-troweled and hand-floated work all the vertical surfaces will shed the water with sufficient promptness to prevent that degree of saturation which would be likely to result from frost. The points to be especially looked to are at the eaves and gables, the projecting portions of a wall, and the joints of windows and doors. A projecting roof will afford sufficient protection to the upper edge of the stuccoed surface. Where the stucco abuts against a projection, like a sill or a lintel, the joint should be closed out to the depth of at least three-fourths of an inch, and the mortar firmly troweled into it. At the points of openings extra care should be taken to secure close adhesion throughout, followed by a careful inspection by sounding and the removal of all spots where the stucco has failed in union with the wall.

Stuhlweissenburg, steel-*shayn-berch* (town), in the county of Fehér, Hungary; on a marshy plain 16 miles S. E. of Lake Balaton (see map of Austria-Hungary, ref. 6-6). It has several fine buildings, a gymnasium, a military academy, a Magyar theater, manufactures of potash, leather, linen, and woollen fabrics, and an extensive trade in oil, wine, grain, cattle, and wool. In its magnificent cathedral the Kings of Hungary were crowned and buried from 1037 to 1527. Pop. (1890) 28,942.

Stumpf, CARL, Ph. D.; psychologist; b. in Wiesentheid, Bavaria, Apr. 21, 1848; educated at Würzburg and Göttingen Universities; became Professor of Philosophy at Würzburg in 1879, at Prague in 1879, at Munich in 1899, and at Berlin 1894; member of the Prussian Academy of Sciences 1895. His principal works are *Über den psychologischen Ursprung der Raumvorstellung* (1873) and *Lehrpsychologie* (2 vols., 1883-99).

J. M. H.

Stupor [= Lat. deriv. of *stupere*, to be struck senseless, whence (by deriv.) *stupefactus*, *stupidus*, dazed, stupidly] that condition in which, when fully developed, the functions of the brain, so far as the mind is concerned, are almost entirely suspended, the individual lying in an unconscious state, though he may still be aroused by vigorous shaking or shaking. When there is complete loss of consciousness the condition is properly spoken of as **COMA** (q. v.). It may be induced by poisons upon the brain, as from a depressed phlegm of bone of the skull or the entrance of some foreign body, as a bullet, by a blow or fall, causing evulsion of the brain or compression from extravasated blood; by the rupture of a blood-vessel, causing cerebral hemorrhage; by the circulation of poisoned blood through the cerebral vessels, as occurs, for instance, when an overdose of opium or alcohol has been taken. Stupor and coma are to be distinguished from sleep by the fact that it is easy to awake a person from sleep, while it is difficult to arouse him from stupor and impossible in coma. In sleep the mind may be active; in stupor it is, as it were, dead. Stupor is a symptom of serious importance in various injuries and diseases

to which the brain is liable. It may exist in all degrees of severity. There is a form of stupor, met with in certain diseases of the brain, in which the individual, though unconscious, is nevertheless not altogether deprived of the power to think and to move the limbs. There is, in fact, a marked degree of restlessness, though the movements are, as it were, automatic, and the speech is incoherent. This condition is known as "coma vigil." It generally only occurs in cases of great gravity, and it indicates a fatal termination.

Revised by W. PEPPER.

Sturgeon [from Fr. *esturgeon*: Ital. *storione*: Span. *esturión* from Teuton. *sturjo*, appearing in O. H. Germ. *sturjo*, *sturo* > Germ. *stör*: O. Eng. *styrja*]: any ganoid fishes of the family *Acipenseridae*. All the species have the body elongated and subcylindrical, or slightly compressed and tapering backward into a rather slender caudal peduncle; the skin is generally armed with minute bony plates, as well as five rows of larger keeled bucklers, one dorsal, one pair lateral, and one pair on the sides of the abdomen; there is no well-defined lateral line; the head is produced into a projecting snout, which is provided below with four barbels in a transverse row; the operculum proper well developed; the mouth is small, inferior, transverse, protractile, with fleshy lips; teeth entirely wanting in the adult; the dorsal fin far behind, and short; the anal still nearer the tail than the dorsal; the caudal with the upper lobe prolonged; ventral behind the center of gravity. The skeleton is cartilaginous. The stomach is not caecal; the pyloric appendages are numerous; the rectum has a spiral valve; the air-bladder is large and simple, and communicates with the oesophagus; two accessory gills occur. Species are found in all the temperate portions of the northern hemisphere. All breed in the fresh water, but some are residents of the sea part of the year, while others are permanent denizens of the lakes and rivers. They nearly agree, in fact, in distribution with the salmonids, save that they are less generally found in streams, on account of their larger size. There are two primary types—(1) *Acipenser*, which embraces several subordinate subgenera or genera; and (2) *Scaphirhynchus*, of which only two species are known, one (*S. platyrhynchus*) confined to the Mississippi river and its tributaries, and another from Central Asia. The number of species of *Acipenser* is about twenty. The most common American species are *A. brevirostris*, or short-nosed sturgeon, and *A. oxyrinchus*, or sharp-nosed sturgeon, which ascend the rivers of the Atlantic slope, and the fresh-water *A. rubicundus* of the Great Lakes and their tributary rivers. Their flesh is reddish, and is by some highly esteemed. Their eggs are often made into caviare; their air-bladders can yield a kind of isinglass. They are the largest of fresh-water fishes, the huso (*A. huso*) of the Caspian and Black Seas and Sea of Azov sometimes exceeding the length of 15 feet and the weight of 2,000 lb. See also FISHERIES and STERLET. For illustration, see FISHES.

Sturgeon Bay: city; capital of Door co., Wis.; on Sturgeon Bay, about midway between Green Bay and Lake Michigan, and on the ship-canal connecting those bodies of water (for location, see map of Wisconsin, ref. 4-F). The bay is 8 miles long by 2 miles wide, and affords an excellent harbor for the largest vessels. The city is in an agricultural and lumbering region, has large shipping interests, and contains a State bank with capital of \$25,000, a private bank, and a monthly and two weekly periodicals. Pop. (1880) 1,199; (1890) 2,195.

Sturges, OCTAVIUS: physician; b. in London, England, 1833; educated at Addiscombe as a cadet in the service of the East India Company; served in India as a lieutenant in the Bombay Artillery; returned to England and entered Emmanuel College, Cambridge, taking the degrees A. B. and A. M. in 1862; entered St. George's Hospital, London; in 1862 became a member and in 1870 a fellow of the Royal College of Physicians; M. D., Cambridge, 1867; lecturer on forensic medicine 1868-71, on materia medica 1871-74, on medicine 1874-93 in Westminster Hospital. He was the author of *An Introduction to the Study of Clinical Medicine* (London, 1873); *The Natural History and Relations of Pneumonia* (London, 1876); *On Chorea and other Allied Movements* (London, 1881). D. Nov. 3, 1894. S. T. A.

Sturgis: village; St. Joseph co., Mich.; on the Gr. Rapids and Ind. and the Lake Sh. and Mich. S. railroads; 31 miles E. by N. of Elkhart, and 36 miles S. by E. of Kalamazoo (for location, see map of Michigan, ref. 8-II). It is in an agricultural region, and contains 9 churches, public, central, and

ward schools, water-works, electric lights, fair-grounds, mile race-track, several large manufactories, a national bank (capital \$65,000), a State bank (capital \$50,000), and a monthly and 3 weekly papers. Pop. (1880) 2,060; (1890) 2,489; (1900) 3,144. State census, 2,834.

EDITOR OF "JOURNAL."

Sturgis, RUSSELL: architect and writer on art; b. in Baltimore, Md., Oct. 16, 1836; studied architecture in New York architect's office and in Europe, and practiced from 1865 to 1878. He then retired on account of feeble health and has since occupied himself with archaeology and fine art, and the work of societies devoted to fine art in New York and elsewhere. Among the buildings designed by him are Battell Chapel, Farnam Hall, Durfee Hall, and Lawrence Hall of Yale College, the Homœopathic Medical College and Flower Hospital in New York, the Mechanics' and Farmers' Bank at Albany, and churches, business buildings and residences in New York, Albany, Aurora, Tarrytown, Watertown, N. Y., New Haven, Farmington, and Littlefield, Conn., Minneapolis, and Louisville. He was editor for decorative art and mediæval archaeology of *The Century Dictionary*, for fine art in general of *Webster's International Dictionary*, and for archaeology and art of *Johnson's Universal Cyclopædia*; otherwise his published writings have been limited to periodicals.

Sturlason, SNORRE: See SNORRI STURLUSON.

Sturm, störm, JOHANNES, von: educator; b. at Schleiden, Germany, Oct. 1, 1507; founded (1537) the gymnasium at Strassburg, which attained, under him, worldwide celebrity. He was generally regarded as the greatest educator connected with the Reformed Church, and received the title *Præceptor Germaniæ*. His work gave a great impulse to the establishment of classical schools. To read, write, and speak Ciceronian Latin was the great object of his instruction, and to this end a course of twenty-one years—six at home, ten at school, five at college or university—was thought about sufficient. D. at Strassburg, Mar. 3, 1589. See Joseph Payne, *Lectures on the History of Education*. C. H. T.

Sturt, Sir CHARLES: explorer; b. in England early in the nineteenth century; entered the army at an early age. In 1828 he was the leader of an expedition organized to explore the interior of Australia, during which he discovered the Macquarie, Castlereagh, and Darling rivers, and soon after led another expedition which explored the course of the Murrumbidgee river, and in June, 1830, discovered the great Murray river, which he followed to its mouth in Lake Alexandrina, returning early in 1831. In 1844 he penetrated to the great stony desert nearly in the center of the continent. He was made registrar-general and subsequently colonial secretary of South Australia. In consequence of his exposure in these expeditions he became totally blind, and returned to England, where he was knighted a short time before his death. He published *Two Expeditions into the Interior of Southern Australia in 1828-31* (1833) and *Narrative of an Expedition into Central Australia in 1844-45* (1849). D. at Cheltenham, England, June 16, 1869.

Revised by M. W. HARRINGTON.

Sturzenbecker, stoorts'en-bek-ker, OSKAR PATRICK (*Oskar Odd*): writer; b. in Stockholm, Sweden, 1811. He was from the first one of the warmest advocates of the union of Scandinavian countries, on behalf of which he began to write in 1830. His greatest success was achieved in the light feuilleton style imitated from the French, in which he has never been equaled in Sweden. His best sketches are collected in *Grupper och Personager från igår* (Groups and Persons from Yesterday). He was also the author of lyrics that display patriotic warmth and a deep sympathy for human progress. D. near Helsingborg, Feb., 1869. Selected works were published at Stockholm in 1878.

D. K. DODGE.

Stuttering: See STAMMERING.

Stuttgart, stöot'gäart: capital of the kingdom of Württemberg, Germany; on the Nesenbach, an affluent of the Neckar; 38 miles E. S. E. of Carlsruhe (see map of German Empire, ref. 7-D). It lies in a charming valley among hills covered with forests and gardens, and is regularly and beautifully built. The Altstadt, occupying nearly the center, and grouped around the market-place, contains several small and narrow streets, but the new parts of the city, mostly erected during the nineteenth century, have broad and beautiful streets and symmetrical squares. The most prominent part is the palace square, ornamented with gardens and fountains containing the jubilee column, over 50 feet high, and surrounded by magnificent buildings. Among these the new

palace is the most remarkable—a very handsome structure, with two projecting wings, the central building containing 164 rooms rich in works of art by Danneberg, Gengenbach, Thorwaldsen, and others. To the right of this edifice stands the old palace, built 1573-79, a gloomy castle with towers and pinnacles, but containing a beautifully painted chapel and large hall, the curious Reichensteine, a spiral horse-path giving access to the third floor, and in the court the equestrian statue of Knecht, the first Duke of Württemberg. In the left wing of the new palace is the royal theater, finished in 1846, and opposite the palace is the Königsplatz, a beautiful structure with an Indian colonnade, built 1855-59, and containing numerous shops, elegant *cafés*, a concert-hall, and other assembly-rooms. In the rear of the old palace is the Schiller Square, containing the statue of the poet, the enormous building of the palace of the prince, and the park church, erected 1490-99, and restored in 1847. One of the most beautiful and most important streets is the Neckarstrasse, running from the palace square in a northwestern direction, and containing the museum of natural science with a rich collection of mammals; the national library, comprising 400,000 volumes, 5,000 manuscripts, 2,300 incunabula, and a collection of 8,700 Bibles in eighty-nine different languages; the museum of art, containing an art school and collections of paintings and statues, etc. Nearly parallel with the Neckarstrasse runs the Königstrasse, traversing the palace square and dividing the city into two parts, a southwestern and northwestern; on this are the royal stables and the royal central hall for commerce and industry, with a good library and important collections. Other remarkable buildings are the museum for Württembergian antiquities, the polytechnic school, the new market-hall; and among the churches, the Landhard's church, Johann's church, a Roman Catholic church, an English church, and the magnificent synagogue. The finest promenade is the palace garden, a park with lakes, fountains, statues, etc., stretching from the palace for the distance of about 2 miles. In the vicinity are the royal summer palaces, Solitude, Villa Rosenstein, Wilhelms, and the Villa, and the charming town of Cannstadt-on-the-Neckar, with 12,000 inhabitants, much frequented as a bathing-place, connected with the city by a railway. The industry in woolen manufactures is important; a wholesale cattle-fair is annually held in August. The manufactures of games, carriages, chocolate, sugar, and machinery are also considerable. The commerce of the city is extensive; the bank and art trade is especially important. Pop. (1890) 125,212. The name *Stuttgart* first occurs in history in 1229, though the exact date of its foundation is not known. It became the residence of the Count of Württemberg in 1329, and the capital of the country in 1482. The city was held by Austria from 1519 to 1594, and occupied by Alba in 1546 on the Smalkalde war. In the period from 1624 to 1638 one-half (5,519) of the inhabitants died from the plague. In the wars of Louis XIV. it was taken by the enemy three times; also several times during the wars of Napoleon.

Revised by M. W. HARRINGTON.

Stuyvesant, st'v'e-sant, Peter: director-general of New Netherlands; b. in Holland in 1602; served in the West Indies; was director of the colony of Caracas; lost a leg in an attack upon the Spanish island of St. Martin; returned to Holland in 1644, and in 1647 was sent to the New Netherlands as director-general. Upon his arrival at New Amsterdam (now the city of New York) in May, 1647, he made peace with the Indians, and a few years later arranged the boundary-line between the Dutch and the English possessions in North America. In 1651 the Dutch built a fort on the site of the present Newcastle, Delaware river, which the Swedish governor Rising captured in 1654. In 1655 Stuyvesant sailed for the Delaware with seven vessels conveying 600 or 700 men, recaptured the fort, and took possession of the entire colony of New Sweden. In the meanwhile discontent had sprung up against the arbitrary administration of the Dutch West India Company, and in 1655 a convention of two delegates from each settlement in the colony assembled and demanded that obscure and obsolete laws should not be revived, and that no officer should be appointed except with the approbation of the people. Stuyvesant replied that the magistrates derived their authority from God and the Dutch West India Company, and not from a few ignorant subjects, and ordered the convention to disperse under pain of condign punishment. The discontent, however, still continued. The English colonies in New England, in spite of the repeated remonstrances of the

governor, began to encroach upon the boundaries of New Netherlands. In 1664 Charles II. of England issued a charter to his brother, the Duke of York, afterward James II., bestowing upon him all the country between the Hudson and the Delaware, including New Netherlands as well as some territory which had previously been granted to the New England provinces. In August of that year, although England and Holland were at peace, Col. Nicolls with an English fleet, appeared in the bay and demanded the surrender of New Amsterdam. Stuyvesant at first refused, but the municipal officers, seeing little hope of successful resistance, and having no very warm attachment to their Dutch masters, insisted that he should yield, and the town was surrendered Sept. 8, 1664, and its name changed to New York—a designation soon extended to the whole province of New Netherlands. Stuyvesant went to Holland the next year, but returned soon after, and passed the remaining eighteen years of his life at the farm, called the *Flower*, which has given its name to the street called the Flower. D. in Aug., 1682.

Revised by J. M. GARDNER.

Sty, or **Harde'olum** [sty = G. *hag*, *stymed*, swelling; *adjuv*, *adjuv*, etc.]: a small leaf which occurs on the edge of the eyelid. It should be treated with a warm-water dressing or light wet poultice; after the discharge of a little pus and a scab, it usually goes well at once. If there be a long succession of these, as sometimes happens, iron and quinine, with occasional mild laxatives, will be useful.

Style, or **Stylus**: See **Pen**.

Style, Old and New: See **CALENDAR**.

Styllis: See **PELAGIC SAINTS**.

Styllis, St. Klement: See **ROMAN SYLLATES**.

Stylopide: See **STREPTOMETER**.

Styptic: See **BLEEDING**.

Styrac'cea (named from the typical genus *Styrax*, from Lat. *styrax* = Gr. *styrax*, storax, or the tree yielding it): a family of exogenous, gamopetalous trees and shrubs, with the stamens commonly monadelphous or polyadelphous, and adnate to the base of the corolla; the calyx more or less adnate, and the seeds few and large with a bony coat; the leaves alternate entire, serrate, membranous, or coriaceous feather-veined. There are about 200 species distributed among seven genera, the most important of which are *Dalson* and *Styrax*. The former is the **SHOEWEE-TREE** (q. v.). *Styrax* contains over sixty species, restricted to the warmer parts of Asia, Europe, and America. Many of the species yield valuable gums, such as *Styrax* (q. v.) and storax. The latter is a solid resin resembling vanilla in color, obtained from *N. officinalis*, a small tree of Asia Minor and Syria. Liquid storax is a balsam obtained from the inner bark of *Liquidambar orientalis*. It is used in making incense and perfumery. Its chief market is in the East.

Sty'ria (in Germ. *Steiermark*): province of Austria; bounded N. by Upper and Lower Austria, E. by Hungary, S. by Carniola and Croatia, and W. by Carinthia and Salzburg. Area, 8,679 sq. miles. In the southern part, on some of the plains, and in the valleys are raised wheat, maize, tobacco, flax, hemp, wine, and fruit; elsewhere the province is mountainous, and cattle-rearing, dairy-farming, mining, and manufactures of metallic wares are the principal branches of industry. The Scler Alps cover the surface between the Enns and the Mur; the Styrian Alps, between the Mur and the Drave; and the Carnic Alps, between the Drave and the Save. These mountains rise to a height of between 7,000 and 8,000 feet, and are rich in iron, copper, salt, alum, marble, and coal. Pop. (1890) 1,282,708, of whom over 710,000 are of German and the rest of Slovenian descent. Capital, Gratz.

Revised by M. W. HARRINGTON.

Styrian Literature: See **SCOTICAN LITERATURE**.

Styx (Gr. *Στύξ*, the hateful): in Greek mythology, a river of Hades which flowed from the tenth source of Oceanus. At the entrance to Hades was the abode of the nymph or goddess Styx, by whom the most solemn oaths of the gods were sworn, thus dedicating themselves to death in case of perjury.—*STYX* was also the name of the highest waterfall (not, as Herodotus says, a fountain) in Greece, near Nemea in Arcadia. The ancients, like the modern residents of the vicinity, considered its waters fearfully poisonous, and it was believed that no vessel could hold any of it unless made of the hoof of an ass or horse. The ancients associated this waterfall with the mysterious *Styx* of the lower world.

Revised by J. H. B. STRECHER.

Suabia: See **SWABIA**.

Suakim, swaa-keem', or **Sawakin**: fortified town of Nubia and best port on the Red Sea; on an island a few hundred feet from shore; lat. 19° 7' N. (see map of Africa, ref. 3-G). It has been in the possession of the British since 1882. Formerly the head of the caravan routes into the interior, it lost much of its importance as a result of the Mahdist rebellion, and this is not yet recovered, because of the insecurity of the interior. The influence of the British hardly extends beyond the reach of their cannon. Opposite Suakim on the mainland is the suburb of El-Kef, also fortified, connected with the city by a low bridge and short railway. The latter is all that was made of a railway projected to Berbera on the Nile in 1884, but prevented at that time by the Mahdists. Suakim is considered of great strategical and commercial importance, and is the most suitable terminus for a railway into Egyptian Sudan. The chief exports are gum arabic, silver, ivory, senna, and skins.

MARK W. HARRINGTON.

Subcarboniferous Series: in American geology, the lowest group of Carboniferous strata. It occupies the interval between the Devonian system and the coal-measures. Earlier designations of the same division are mountain limestone, Carboniferous limestone, and Lower Carboniferous, and a later proposed title, Mississippian series, has much to commend it. In the Mississippi valley it consists principally of limestones and shales, and includes, in an ascending order, the Kinderhook, Burlington, Keokuk, Warsaw, St. Louis, and Chester formations or groups. In Pennsylvania the equivalent series consists principally of sandstone and shale, having a maximum thickness of 5,000 feet. The series has also been recognized in Nova Scotia and New Brunswick, and has a great development in the Rocky Mountain region. The fossils are principally marine invertebrates, some of which, especially the brachiopods, are of worldwide distribution. Remains of fishes and of reptiles also occur. Rocks corresponding to the Mississippian series in time have a wide distribution in other countries, and especially in Europe. See **CARBONIFEROUS PERIOD** and **DEVONIAN PERIOD**.

ISRAEL C. RUSSELL.

Subconscious States: states of mind which belong to us and which we can pay attention to, but which we may not be actually thinking of; such as our sense of the furniture in the room about us. Such states or elements are very common in our mental history, and are called subconscious as long as there is evidence that they have not sunk entirely out of the whole of our present state of mind. On the other hand, things which we may merely remember on occasion, and are in no sense conscious of at a particular moment, are then "unconscious." See **UNCONSCIOUS STATE**. J. M. B.

Suberic Acid [*suberic* is from Lat. *sub'er*, cork-tree, cork]: a homologue of oxalic and succinic acids. Its general characters are those of that family of dibasic acids, and its empirical formula is $C_8H_{10}O_4$. The name was originally due to the fact that this acid was first obtained by the action of nitric acid on cork. Fats generally, however, yield it by the same treatment, and it is by no means a characteristic product of cork. To obtain suberic acid free from the other acids produced by the action of nitric acid on fats, the mixed product is treated with cold ether, in which this acid is almost insoluble. It is necessary, however, to purify it further by recrystallization. It may be obtained in large needles, which sublime like oxalic acid. It is sparingly soluble in cold, but easily in boiling water, and soluble in alcohol.

Revised by IRA REMSEN.

Suberine: See **CORK**.

Subiaco, sôo-bêe-aa'kô (anc. *Sublaqueum*): town; in the province of Rome, Italy; on the right bank of the Tevere; 42 miles E. N. E. of the city of Rome (see map of Italy, ref. 6-E). It derived its name from its situation below a villa belonging to Nero, in the grounds of which were three lakes. In the monastery of Santa Scolastica, founded in the fifth and restored in the tenth century, the printing-press was first used in Italy, a Lactantius (1465) being the first issue. The monastery of St. Benedict, the first founded by the saint himself, was rebuilt in 817. Pop. 6,503.

Subinfeudation: See **LANDLORD AND TENANT**.

Sublimation [from Lat. *sublimare*, raise, deriv. of *sublimis*, lifted up, on high]: a chemical process of separation and purification, applicable only occasionally in cases in which a volatile substance condenses or crystallizes from the condition of vapor directly to the solid condition, and

not to the usual liquid form. In such cases this method of obtaining bodies in pure and crystallized form is highly convenient and valuable. Among the more important substances to which this method is applicable are sulphur, iodine, vermilion, corrosive sublimate, calomel, salts of ammonia, arsenious oxide, oxalic, benzoic, succinic, and pyrogallic acids, camphor, caffeine, etc. As those substances which volatilize at low temperatures will readily pass through porous diaphragms like paper when in a vaporous state, it is often convenient to cover the lower vessel, containing the substance to be volatilized, with paper, which will prevent the crystals that condense in the head or upper inverted vessel from falling back and causing waste of time. In cases of bodies requiring high temperatures wire-gauze screens may be employed in the same way. Revised by IRA REMSEN.

Sublime [from Lat. *sublimis*, lifted up, lofty, sublimis]: Contradistinguished from the beautiful, which charms and attracts us, the sublime awes us, moves us with a feeling of pleasure mixed with fear. The sublime in nature is usually found in the boundless expanse of the ocean, in the resistless might of its waves when moved by a storm, or more frequently in the thunder-storm with its threatening look, its vivid and destructive lightnings, and its deafening crashes of thunder. Still more adequate is the manifestation of the sublime in instances of moral heroism—in deeds of daring and self-denial; the sublime in art has most frequently made use of this phase. Kant, in his *Critique of the Judgment* (§ 23-53), has given the first thorough and systematic treatment of the sublime. According to him, "while the beautiful in nature appertains to the form of an object—hence to its circumscribed limits—the sublime, on the contrary, is to be found also in formless objects; a want of limitation attaches to it. It is, however, represented as a whole, and not as something merely fragmentary. The beautiful may therefore be regarded as the portrayal of an idea of the understanding (not a mere concept), but the sublime is rather the portrayal of an idea of the reason, which, from its nature, can not be adequately represented by material things." "The pleasure of the beautiful appertains to the quality of an object, while the sublime is manifested chiefly in the quantitative aspect of it." "To the charm of the beautiful there is frequently joined a sportiveness, but the sublime is always earnest." "The sublime, in its proper form, is not presented in a sensuous manner, but concerns only ideas of the reason, whose very incommensurability with sensuous forms, being exhibited, stirs the heart." "The beautiful pleases us immediately, but in its presence we feel disinterested; the sublime pleases us, but through its hostility to our sensuous interests." Cousin (*On the True, Beautiful, and Good*, lecture vii.) says: "A beautiful object is something completed, circumscribed, limited, which all our faculties easily embrace, because the different parts are on a somewhat narrow scale. A sublime object is that which, by forming not in themselves disproportional, but less definite and more difficult to seize, awakens in us the sentiment of the infinite." Hegel (*Æsthetics*, 2d part, div. i., chap. iii.) makes the sublime a province of symbolic art, whose chief function is to portray the purification of spirit and its separation from the world of sense and all visible existence. "The highest principle is regarded as existing apart by itself, and as incapable from its very nature of finding adequate expression in the finite appearances of the real world." "The sublime arises in an attempt to express the infinite without finding in the domain of visible phenomena an object capable of representing it. The infinite elevates itself above particular existences, considered either in themselves or in their totality; they are as nothing before it; and the positive relation which sensuous objects have to the beautiful, in the sublime changes to a negative relation which is more in conformity to the divine nature. God is thus represented as purified of all contact and participation of visible appearance." "In the Orient, in India, the One, or Substance, is conceived as immanent in contingent existences created by it; they are portrayed as mere instruments of the divine power, or as mere ornaments for the display of the glory of the Absolute." In the *Bhagavad Gita* (ch. xi.) the vision of the Universal Form of Vishnu furnishes us the highest example of this phase of the sublime. The speech of the *Erdgeist* in Goethe's *Faust* is an example quite similar in form and content. In Hebrew poetry Hegel finds the highest realization of the sublime: "Jehovah is not 'immanent' in nature, but 'transcendent'."

—lord over the universe—and in his presence the entire creation is devoid of power and sinks into nothingness. The grandeur of the Lord is revealed by the fact that the real world, with all its splendor, pomp, and magnificence, is a mere accident, an instrument, an ephemeral appearance in comparison with the eternal and immutable Being. In the 104th Psalm God is represented as covering himself with light as with a garment, and as stretching out the heavens like a tent. 'He layeth the beams of his chambers in the waters; he maketh the clouds his chariot; he walketh upon the wings of the wind: he looketh on the earth, and it trembleth; he toucheth the hills, and they smoke. He laid the foundations of the earth, that it should not be removed forever.' In the psalm of Moses (Ps. xc.) the finitude of man furnishes the contrast which makes the portrayal of the omnipotence of God sublime." For other but less adequate treatises on this subject, the reader is referred to the writings of Burke, Dugald Stewart, and Addison. The famous treatise of Longinus (*Περὶ Τρύφους*) should not be omitted.

WILLIAM T. HARRIS.

Submarine Navigation [*submarine* is from Lat. *sub*, under + *marine*, from Lat. *marinus*, deriv. of *ma're*, sea]: the art of navigating a submerged vessel. In submarine navigation it is requisite that an operator should be able to move freely in any direction and at any depth, and with no communication with the surface except at long intervals. The accounts of early attempts to accomplish these results are exceedingly meager. William Bourne, of London, is mentioned as proposing a plan in 1578, and Cornelius Drebbel, in 1624, is said to have constructed a submarine boat to carry twelve rowers, besides passengers, and also to have discovered a liquid which had the property of restoring air when it became impure by breathing; but he died before his plans were perfected, and his secret died with him. Papin and Borelli are mentioned in 1672, and Stapleton in 1693; but little was apparently accomplished till 1771, when David Bushnell first suggested the idea of attacking a vessel underneath the water, and constructed a submarine boat capable of accomplishing the desired object. There is no drawing extant of this remarkable invention, but the accompanying figure corresponds with the descriptions, which are quite accurate, and will serve to illustrate an invention which, for the purpose for which it was designed, was the most perfect thing of its kind that has ever been invented. The boat was shaped like a turtle, and floated in the water with the tail down. It contained air enough to support life for half an hour, and air could be renewed at the end of that time through small ventilators by rising to the surface. The operator was seated in the middle, the seat forming a brace between the two sides, and in this position he had his eyes opposite one of the numerous glass plates in the cover or top of the boat. In front of him was the handle of a screw, by which the boat was propelled; another, by which it was raised or lowered; a compass marked with phosphorus; a water-gauge, to show the depth, marked with oil and phosphorus; and near him the handles or treadles of various small pumps and levers, by which water and foul air were expelled, the rudder moved, ballast let go, etc. The torpedo—or submarine magazine, as Bushnell called it—consisted of a block of oak containing a charge of about 150 lb. of powder. This block was on the upper after

underneath the bottom, fasten the torpedo by means of the screw. The torpedo and screw were then detached from the

FIG. 2.—Bushnell's submarine boat: elevation.

operator's boat, a clock-work mechanism inside the torpedo being set going at the same time. This clock-work could be set for six, eight, or twelve hours' run, thus allowing the operator ample time to make his escape. See TORPEDOES.

In 1845 a shoemaker of Michigan City, Ind., named Phillips, devised a submarine boat in which he made frequent descents, sometimes taking his family. In 1864 occurred the only successful use of a submarine boat in warfare, when the U. S. S. *Housatonic* was sunk by a spar-torpedo carried by a Confederate "David," a cigar-shaped boat built of boiler-iron and having a crew of nine men, eight of whom worked the propeller. This boat is, however, supposed to have been only partially submerged when the attack was made. She was sunk with her entire crew by the explosion of her own torpedo. About the same time the French Government tried a boat called the *Plongeur*, designed by Admiral Bourgeois and M. Brun. This vessel was of about 200 tons displacement and propelled by 80 horse-power compressed-air engines. Her depth of immersion was to be regulated by the admission or expulsion of water, but horizontal rudders of large area were found a better means of attaining this end, and a vertical

FIG. 1.—Bushnell's submarine boat: plan.

part of the boat and connected by means of a rope to a wood screw, the handle of which was directly in front of the operator. The mode of operation was to move slowly along the surface, with the top just awash, till within a short distance of a vessel at anchor, then to sink, and, coming up

screw worked by hand was afterward added to assist in the depth regulation. Although since Bushnell's time many inventors, including Fulton, have turned their attention to submarine navigation, little real progress was made for over a century. The principal naval powers, however, have conducted experiments looking to the adoption of submarine boats for war purposes, and it has been shown that submarine navigation is feasible, though opinions differ greatly as to its value for actual service.

In Great Britain the Nordenfolt boats have attracted widespread attention. Their principal features are steam-propulsion on the surface, the use of the reserve heat stored in the water and superheated steam for propulsion under water, and submergence by vertical screws. The first boat, built in 1883 and sold to Greece, had a surface speed of 9 knots. The second and third boats were of 160 tons displacement, with 12 knots surface speed, and were built for the Turkish Government. The fourth boat embodies numerous improvements over her forerunners. Her displacement is 250 tons submerged and 160 tons when running on the surface. Engines of 1,000 horse-power give a speed of 15 knots on the surface, and the heat stored in her boilers, which contain 27 tons of hot water, furnishes power for a submerged run of about 20 knots at 5-knot speed. Submergence is effected by vertical screws, working in wells, one at each end of the boat, and actuated by separate engines, the boat being first brought awash by filling certain compartments with water. The reserve buoyancy is never less than half a ton, and can be increased by expelling the water by powerful pumps. In the conning-tower are placed the necessary connections for controlling the machinery for driving and steering the vessel, sinking or rising, and for discharging the Whitehead torpedoes with which she is equipped.

In France, where perhaps the greatest advance in the art of submarine navigation has been made, the Goubet boats, a number of which are said to have been bought by Russia, succeeded the Plongeur. These are very small boats and originally were driven by hand-power, though in the

Holland, of New York, have been tried. The essential feature of the Baker boat is the use of two screws on a transverse shaft through the center of gravity of the boat, these screws being susceptible of movement so that the thrust developed by their rotation can be directed at will in any plane at right angles to the shaft. The motive power is electricity from storage-batteries, and submergence is effected and maintained by giving the screws a sufficient angle to overcome the buoyancy by the vertical thrust and at the same time propel her by the horizontal component. This plan renders it less important to preserve horizontality of the boat's axis than in a boat whose motive power is at the stern, but it has the disadvantages of being wasteful of power and of placing the screws in a greatly exposed position. The Holland boat, which has been, perhaps, as successful as any yet built, is shown in the drawing. She was 31 feet long by 6 feet in diameter, circular in cross-section, and weighed 18 tons when submerged. The motive power was obtained from a petroleum-engine which gave a surface speed of 8 knots and a submerged speed of about 6 knots. Reservoirs containing 240 cubic feet of air at 340 lb. per square inch supplied the air necessary for breathing purposes, for the engine, for the propelling charge of a gun fixed in the bow, and for expelling water from the water-ballast tanks if it became necessary to ascend quickly to the surface. The engine-compressor, drawing its air directly from the living space, gave sufficient ventilation. The essential feature of this boat was the use of diving-rudders on a horizontal shaft at the stern, to produce and maintain submergence, the boat being steered in a vertical direction just as an ordinary boat is in the horizontal plane. The practicability of this method was proved by numerous dives in water of various depths, and it was found possible to maintain a nearly constant depth either by hand-steering or by an automatic device similar to the depth-regulator of a Whitehead torpedo. A camera-lucida projecting above the water gave a clear view while the boat was running several feet below the surface.

FIG. 4.—Vertical longitudinal section of Holland's submarine boat: a, submarine gun and projectile; b, firing-charge chamber; f, automatic air-pressure regulator; gg, water-ballast tanks; j, camera-lucida.

later ones an electric motor working from accumulators is used. The submerged displacement is 2 tons and the speed 5 knots. Trim is preserved by water-tanks at each end connected by a pump which transfers water from one to the other on being started by the automatic action of a pendulum. The crew of two men are provided with sufficient air, from a reservoir at 50 atmospheres pressure, for ten hours. The screw is fitted with a universal joint so that the propelling power can be applied to changing the course in any direction. The armament consists of a torpedo carried outside the boat and intended to be released at the proper moment so as to rise under the enemy's bottom and there be exploded by a wire leading to the boat after she has withdrawn to a safe distance. The utter impracticability of this method of attack is evident. A later French production is the Gymnote, of 30 tons displacement, spindle-shaped, and 56 feet long by 6 feet maximum diameter. This boat was so successful that a larger boat of the same general design, and named after the inventor, Gustave Zédé, was also ordered. The Gymnote is propelled by a 55 horse-power electric motor worked by accumulators, submergence being effected by filling water-compartments until she has only a slight buoyancy and then causing her to dive by means of horizontal rudders. She has a speed of 10 knots and is worked by a crew of three men. An electric gyroscope indicates angular movements in the horizontal plane, and enables her to maintain a fixed course beneath the surface.

In the U. S. two improved types of submarine boat, invented respectively by George C. Baker, of Detroit, and J. P.

In 1892 an appropriation of \$200,000 was made to enable the Navy Department to build and test a submarine boat, and Mr. Holland's plans for a boat of about 150 tons displacement were adopted. This boat differs from that above described in having a 70 horse-power electric motor, worked from storage-batteries, for under-water propulsion. Her surface speed was designed to be 15 knots, with 1,000 horse-power steam-engines actuating twin screws, and her submerged speed 8 knots for six hours. An automatic device controlling the vertical rudders enables a straight course to be held under water. The armament adopted consists of Whitehead torpedoes expelled from a pair of bow tubes. In addition to the diving-rudders this boat has a vertical screw at each end actuated by an 8 horse-power electric motor to maintain submergence when not moving. An important feature is an automatic safety device by means of which, when a dangerous depth is reached, air is admitted into a bow compartment, expelling a large quantity of water, and, by raising the bow, changing the course upward.

General requirements for submarine boats for war purposes—and this is their only practical use—stated in the order of their importance, are safety, facility of maneuver, speed, endurance, and offensive power. For safety the boat must have strength to resist the crushing force of the greatest depth to which she will descend, and must possess a reserve buoyancy, overcome during submergence by mechanical means but never destroyed. She must have stability enough to prevent capsizing or considerable change of trim

under service conditions and must carry an ample supply of air for the crew. Modern steel construction enables the necessary strength for a submergence of 150 feet, which is ample, to be obtained with a weight of hull of about one-half the displacement. Reserve buoyancy is a feature of all modern submarine boats, and additional safety is given by various devices whereby the pressure due to any stated depth will automatically impel the boat upward, either by expelling water from the tanks or by moving the horizontal rudders. Stability on the surface is obtained as in ordinary vessels, and below the surface by simply placing the center of gravity below the center of buoyancy. Compressed air in tanks gives a ready means of ventilation, but in a boat of ordinary size there is enough air to last the crew several hours, especially as the storage-batteries generally in use for propulsion under water give off a certain quantity of oxygen.

Complicated means for purifying the air are found to be practically not necessary. Facility of movement in the vertical plane can probably be best obtained by diving-rudders, for with these a boat can most quickly come to the surface and again disappear. Any simple form of pressure-gauge will indicate the depth of submergence, and the variations of the water-pressure are easily made to control the diving-rudders automatically, the replacement of fuel, torpedoes, or other stores expended by an equal weight of water keeping the buoyancy and trim unchanged. Motion in the horizontal plane is controlled by ordinary rudders and twin screws add to the turning power. Surface speed is of great importance, since approach to an enemy must be on the surface, and escape may depend upon it. Steam propulsion is still the best for surface use, means being provided for rapidly housing the smoke-stack and sealing the furnace-doors preparatory to diving. Endurance depends only on the weight which can be allotted to fuel or other sources of power. Fuel for a run of 1,000 miles on the surface and electric power for a run of 50 miles under water can easily be carried in a boat of 150 tons. For purposes of offense the automobile torpedo is probably most effective, though the submarine gun, using either powder or compressed air as a propelling charge, promises well. Speed under water is best obtained by the use of the electric motor and storage-batteries, the feature of unchanging weights having manifest advantages. With a vessel of good form there should be no difficulty in attaining as great or greater speed than on the surface, but there is no probability that high speeds will ever be used in submarine navigation, the impossibility of seeing anything and the uncertainty of position and direction rendering it necessary to move slowly.

PHILIP R. ALLEN.

Subpoena [Lat. *sub*, under + *poena*, penalty]: in law, a writ or process by which either parties or witnesses are compelled to appear in court or before a judicial officer and answer or testify, as the case may be, under a penalty for their disobedience. There are several different kinds of this writ. In the courts of chancery it was for a long time the ordinary process, issued upon filing a bill of complaint, for the purpose of procuring the defendants to appear and answer. This use, however, was abolished in England some time before the consolidation of the law and equity courts and procedure (see *Courts*), and the defendant in a chancery suit was simply served with a copy of the bill, and with a notice or summons to answer thereon or acknowledging the same. The common species of subpoena now used in all the courts, civil and criminal, is the *subpoena ad testificandum*, for the purpose of ordering witnesses to attend upon a trial or other judicial examination, and to give their evidence thereon. It generally purports to be issued by the court, to be signed by its clerk, and sealed with its seal; but in the loose procedure prevailing in many States of the U. S. it is issued by the attorney. It commands the person in whom it is addressed to lay aside all excuses and pretenses, and to appear before the court or officer at the time and place mentioned, and testify on behalf of the party issuing it, under a penalty in case of a neglect to comply with the order. A variety of

this species is termed the *subpoena duces tecum*, and contains an additional clause directing the witness to bring with him into court certain books, papers, etc., in his possession which may be useful as evidence, and which must be designated with sufficient particularity to apprise the witness of the exact papers to be produced. Both these forms are compulsory; the witness must obey the mandate, and it is for the court alone to decide whether his evidence or the documents he is ordered to produce are material and proper. If the witness violates the command, an action for damages may be maintained against him by the party who is materially injured by his default. The subpoena is served by exhibiting the original to the witness and delivering to him a copy thereof, and paying him his lawful fees for travel and for attendance. Both the subpoena of *testificandum* and the *subpoena duces tecum* may be used by committees of legislatures and other quasi-judicial bodies lawfully constituted for the purpose of carrying on investigations, as well as by courts and magistrates. Revised by F. STOKES ALLEN.

Subrogation [from Lat. *sub*, under + *rogare*, ask]: an equitable doctrine by which a person paying in proper circumstances a debt which is between himself and another should have been paid by the latter is given the rights and remedies of the original creditor. It may be stated as a general principle that whenever a person *voluntarily* liable for a debt pays the same, the demand is not regarded in equity as discharged, but he at once and by operation of the equitable doctrine succeeds or becomes subrogated to all the rights, remedies, and securities which the creditor held against the debtor primarily liable, and may enforce the same as a creditor against such debtor in order to reimburse himself for the outlay which he has made on behalf of that party. The following are some of the most common and important instances which result from an application of this general principle to different facts and circumstances: (1) When a junior mortgagee pays the debt due to a prior mortgagee of the same land he becomes entitled to the prior mortgage, is regarded as its equitable assignee, and can compel its actual assignment to himself. The rule applies to all cases where a junior creditor pays the demand of a prior creditor; he succeeds to the latter's claim and is entitled to all the securities held for its enforcement. (2) When one of several joint debtors pays the entire demand he is entitled to a contribution from the others for their respective shares, and acquires the rights and securities of the creditor against them. (See *Governments*.) (3) The principle is most frequently applied in the case of the surety who pays the demand primarily owing by his principal debtor. He is entitled to recover their contributory shares from his co-sureties, if any, and the entire amount which he has advanced from his principal. To aid him in enforcing these rights he is entitled to hold and use all the collateral securities given by the principal debtor to the creditor. For example, if as such surety he pays off a mortgage debt he is an equitable assignee of the mortgage itself. If the creditor has recovered a judgment against the principal and surety, or against the principal alone, and the surety pays the demand, he is not only entitled to hold this judgment, but he is permitted to enforce it by execution against the principal.

Subsidies [from Lat. *subsidius*, reserve-troops, support, relief; deriv. of *subsistere*, settle down, lie in wait]: (1) in English constitutional history, special taxes assessed upon persons and not directly upon property; (2) in the political history of Europe, payments to an ally, to aid in carrying on a war; (3) the usual application of the term since 1840, grants of money by the state in aid of individual enterprises. The most important subsidies of this kind have been granted in aid of transportation companies.

Railway Subsidies.—In Great Britain the Government granted no subsidies whatever except in Ireland. France defrayed about half the original cost of her railways, and left them to the companies to operate. This policy was followed in most of the other states of Southwestern Europe, as well as by Austria, Russia, and British India. (For the history of direct ownership of railways by the state, see *Transportation*.) In the U. S. the subsidy system has been much more complicated. Railways have been assisted by State and municipal subscriptions in their stock and their bonds, even on an unwisely large scale. National aid to railways, with one important exception, has been in the form of grants of public land. From an early period there had been

important grants of this kind in favor of roads and canals. In 1850 large grants of public land were made to the Illinois Central and the Mobile and Ohio railroads, through the medium of the States of Illinois, Alabama, and Mississippi, Congress for form's sake delivering the land to the States, to be in turn by them delivered to the railway companies. The example was rapidly followed in other parts of the U. S., the system being extended to Missouri in 1852, to Arkansas in 1853, and in 1856 to Michigan, Wisconsin, Iowa, Florida, and Louisiana, besides additional grants to Alabama and Mississippi. It was a game of sectional interests, each part of the republic being anxious to secure its share of the spoil. Some 27,000,000 acres were given to corporations in this way before the crisis of 1857 put a temporary stop to all schemes of the kind.

The civil war, though it stopped railway building, gave a new impulse to the policy of subsidies. California was at that time so far out of communication with the rest of the republic that its adherence to the Union was a matter of sentiment rather than of direct connection. To strengthen this sentiment on the one hand, and to secure the means of communication by land when it was no longer safe by sea, public attention was directed to the project of a Pacific railway, which seemed to be a political necessity, to be obtained at almost any price. The Pacific Railroad Bill, carried by Thaddeus Stevens in 1862, gave to the Union and the Central Pacific railroads a money subsidy amounting to over \$25,000 a mile, and more than 30,000,000 acres of land in addition. The money subsidy took the form of a loan, but it was not expected that it would be repaid. It seemed for a time doubtful whether the road would be built at all; but the work proved unexpectedly easy, and the Cr dit Mobilier, a construction company formed for the purpose of building the road, realized enormous profits, involving a public scandal, since many Congressmen were found to hold the stock of this construction company without having furnished any consideration therefor. The unexpected success of this enterprise made the company profitable, and it might have paid interest on the moneys advanced by the U. S., but, taking advantage of a technical defect in the remedies by which the lien of the U. S. could be enforced, the company evaded this obligation. The Thurman Act of 1878 attempted to settle the matter by providing for the payment to the U. S. of a portion of the earnings of the company, to form a sinking fund which should meet the amount of the debt at maturity; but these earnings proved much less than had been expected.

The Northern Pacific road did not succeed in getting a cash subsidy, like that of the Union Pacific, but its promoters secured a double grant of land per mile, amounting to about 47,000,000 acres in all. The two southern routes secured about 70,000,000 acres, so that there have been granted in aid of railways something like 160,000,000 acres of territorial land. In addition to this, Congress, in the years immediately following the war, renewed the policy of State land grants, renewing those which had been forfeited and adding new ones to the amount of some 30,000,000 acres. Besides these grants of U. S. land, certain swamp and timber lands, which under general laws had been made the property of the States themselves, were also devoted to the aid of railway construction. The nominal amount of land thus granted in aid of railways under various acts exceeds 200,000,000 acres, but only a little more than a fourth of this has been actually patented.

The method adopted in the granting of the lands was ingenious. The whole country being divided into quarter sections of 160 acres each, the U. S. reserved the alternate squares or quarter sections, like the black squares on a checker-board, and granted to the railways only the intermediate parts. On the lands thus reserved by the U. S. the price was at once doubled, so that the treasury was as well off as before, and even better off, since its land came into market more rapidly, owing to the construction of the roads. Meantime, it was ingeniously argued that a settler, so far from being burdened by the change, was better off than before, for he could better afford to pay \$2.50 an acre for land that was near a railway than \$1.25 an acre for land which was wholly out of reach. Thus it was thought that the help might be rendered to the railways without sacrifice of any other interests. Unfortunately, it proved that the system stimulated unsound railway schemes and caused railway building to be misdirected; that the provisions intended to protect the Government interests were disregarded; that the settler was induced to move too far West, where he was, for

the time being, at the mercy of the railway; and that the real gainer by these schemes was usually either the land speculator or the financial operator of the worst sort. The best practical proof of these mistakes is seen in the reaction against land grants which made itself suddenly felt at the time of the granger movement. Since 1872 the policy has been abandoned, though it has been impossible always to enforce forfeitures, even in cases where such a procedure would be clearly just. The whole history of the land grant system, as well as that of municipal subscriptions to railway stock and bonds, gives force to the views of those who disbelieve in Government interference. It appears that business men, as a rule, can judge better than Congressmen of the necessities of the various sections of the U. S., and that the attempts to stimulate enterprise in particular directions, though well meant, have been apt to do harm rather than good. It is probable that the subsidy to the Union Pacific was justified by the result, and perhaps that to the Illinois Central also, but the number of mistakes is largely out of proportion to the number of successes.

A most important system of subsidies has been that of the Dominion Government to the Canadian Pacific Railway. The reasons in this case were a good deal like those for the Union Pacific route in the U. S., and the success of the enterprise seems to have justified the policy of its promoters.

Steamship Subsidies.—Ocean steam-navigation was proved possible as early as 1818, but it was not until many years afterward that the commercial success of any such enterprise was assured. The marine engines of that period were not economical in their construction, and sails furnished cheaper, though less sure, motive power. It was a political necessity, however, for Great Britain to have steamships sooner than any other nation, even if such steamships were for the time being unprofitable. Her colonial possessions were so scattered that every argument in favor of the Union Pacific Railway subsidy in the U. S. applied with vastly greater force to steamship subsidies for Great Britain. In 1838 proposals were asked for a line of Atlantic steamers, and in 1840 the contract was awarded to Samuel Cunard. In 1840 four ships were put on, with an annual subsidy of £81,000. The contract was gradually extended until 1858. It was not until about 1870 that it was gradually reduced. About the time of the establishment of the Cunard subsidy a contract was made with the Peninsular and Oriental Steamship Company for the carriage of the mails to Gibraltar, and this contract was afterward extended so as to secure the carriage of the mails by the same company to Alexandria, Calcutta, Bombay, and finally to Australia. In 1840 a contract was also made with the Royal Steam Packet Company for the carriage of mails to the West Indies, and afterward to South America. At the time when the subsidy system was most largely developed, the British Government was spending in round numbers £1,000,000 annually for the conveyance of the mails—a sum which has been reduced to about £700,000 annually.

To the Cunard Company and to the Royal Mail Company these contracts were unquestionably of great value. In the case of both these companies the price paid was sometimes much more than the service was commercially worth. If proof were needed, this is shown by the fact that the Inman line, established in 1850, has worked successfully without the aid of subsidies. Other unsubsidized companies of the same sort soon followed, and ultimately public sentiment forced the Government to reduce the payments to the Cunard line. The Peninsular and Oriental Company was not quite so liberally dealt with as the two other great subsidized lines. In many cases it would appear that the special requirements as to construction, sailing ports, and penalties for delay almost offset the advantage of a subsidy. Great Britain was paying not for mail contracts but for military strength, and she got what she paid for, and on the whole she got it cheaply. In one instance, at least, that of the Galway and the Anchor line, a subsidized line failed in the competition with an unsubsidized one.

The admiralty subsidies in Great Britain are at present £33,847 annually. Besides this, the payments for carrying the mails in the fiscal year 1893-94 were £710,585, which is about £450,000 in excess of the receipts for sea-postage.

The U. S. did not want Great Britain to get the start in ocean steam-navigation. In 1841, two years after the first Cunard contract, there was an agitation in favor of similar action on the part of the U. S. In 1845 the Postmaster-General was authorized to make contracts for the conveyance of foreign mails in steamships sailing under the U. S.

flag. A line to Bremen was established under this act in 1847. In the same year an act was passed requiring the Secretary of the Navy to arrange for U. S. steamships to carry the mail from New York to Liverpool, to the West Indies and Gulf ports, and from Panama up the Pacific coast. From these contracts arose the Collins line and the Pacific Mail Steamship Company, besides others less important. By act of 1851 provision was made for the Panama Railroad, and in 1852 the Collins line subsidy, originally \$250,000, was increased to \$350,000 annually. In 1853 the payments for U. S. foreign mail service amounted to about \$9,000,000. The Collins line was the most important enterprise, and for the time being the most successful. It had the fastest and best steamships of their period, built of oak, and relying on paddle-wheels as their motive power. The subsidy was \$25,000 a voyage, or \$4.70 per mile run. The average speed attained was nearly half a day better than that of the Clippers. In 1854 the Arctic was sunk in a collision, and the Pacific disappeared in 1856. Such was the effect of these accidents that, in spite of the subsidy, it was no longer possible to run the Collins line, and the field was left to the British steamers. At the outbreak of the civil war the U. S. lines to Europe were withdrawn. In 1864 arrangements were made for subsidizing a line to Cuba and Brazil. In 1865 the Pacific Mail Company was offered large inducements to extend its lines to China and Japan; \$150,000 annually was spent for the Brazil line; \$500,000 for the China and Japan lines. In 1869 an attempt was made to establish a European line with a subsidy of from \$400,000 to \$600,000 a year, but it failed because the mail service provided under this act would have been inadequate. In 1872 an attempt was made to increase the subsidies in the Pacific Mail and Brazil companies. But the reaction was close at hand. An investigation into the history of the means by which these appropriations were secured brought such scandalous corruptions to light that no Congressman dared to vote for the continuance of a policy of this kind. Meantime the Pacific Mail Company had been unfortunate in every way. Prior to 1865 it had been a sound concern. When the subsidy was increased it fell into the hands of speculators. The stock fell from par to below 40. The money under the supplementary contract of 1872 was not earned by the company, owing to its failure to construct the vessels at the appointed time. In 1875 the Brazilian and Pacific mail subsidies expired, and hardly a voice was heard in favor of their renewal. In the year 1879 a strong effort was made to secure renewed subsidies for a Brazilian steamship line, but without success. It was not until 1891 that the efforts to secure profitable mail contracts for American lines met with anything like success. By an act of Mar. 3 of that year the Postmaster-General was directed to make arrangements with U. S. steamship companies, whose vessels were so constructed that they could serve as naval auxiliaries in case of war, to carry the U. S. mails at a rate not to exceed \$4 a mile run with first-class vessels—i. e. vessels of not less than 8,000 tons register and 20 knots an hour ordinary sea speed. Vessels of lower classes in tonnage and speed were limited to \$2, \$1, and \$0.60 per mile for successive classes. Mail contracts for service between the U. S. and Great Britain were only to be made with vessels of the first class. A number of lines to South American ports took advantage of these contracts, and the Pacific Mail and Oceanic companies arranged for a considerable Pacific service on this basis; but it was not until the autumn of 1893 that the International Navigation Company made an arrangement for first-class European service (in connection with the admission of the Paris and New York to the U. S. register).

To U. S. steamships carrying mails without special contract an advantage is given by paying them \$1.50 a pound for letters and post-cards and 5 cents a pound for other articles, instead of 44 cents and 4½ respectively, which are the rates paid foreign vessels. The total ocean mail payments of the U. S. in the year 1893-94 were as follows:

ARTICLE	U. S. vessels	Foreign vessels
Transatlantic service	\$196,732	\$425,170
Transpacific service	240,735	11,600
Other transoceanic service	281,965	25,000
Total	\$719,432	\$461,770

The Dominion of Canada voted a subsidy of \$150,000 to the Canadian Pacific Railway for its service to China and Japan, and a few years later (1893) it voted \$150,000 for a transatlantic steamship line.

Germany has paid subsidies to mail-steamers amounting in 1902 to 1,000,000 marks, or \$1,540,000—averaging about \$1.25 per mile run—besides regular payments at low rates for mail passages on ordinary routes.

France has adopted a much more comprehensive system of shipping bounties. It includes payments both for construction and navigation of steam-vessels, whether they carry mails or not. By the act of 1890 the construction bounties are as follows:

Iron and steel vessels	As France lost steam ton.
Wooden vessels	Over 150 tons 40 "
	Under 150 tons 30 "
Engines and boilers	15 francs per 100 h.p.

In addition to this there are navigation bounties for vessels engaged in foreign trade. For those engaged in the "distant" trade (beyond Gibraltar or the Suez Canal) these bounties are as follows: per 1,000 nautical miles run:

VESSELS	First year francs per ton	Maximum for each successive year
Steel or iron, steam	1.40	0.4
Wooden, steam	1.10	0.3
Steel or iron, sail	1.70	0.5
Wooden, sail	1.50	0.3

In order to earn this bounty these boats must be built in France and almost entirely manned by French sailors. The act of 1891 allowed one-half the regular rate of navigation bounty to foreign-built ships run under the French flag, but this was withdrawn by the act of 1901. Vessels in the short-distance foreign trade earn two-thirds of the amount above given. The average annual payments under the act of 1891 were: Construction bounties, \$570,000; navigation bounties, \$1,540,000. The act of 1901 was more successful in encouraging navigation than in encouraging construction.

Italy has a combined system of construction and navigation bounties. The construction bounties are nominally in the form of a tariff rebate on materials used; but as this rebate is purposely made larger than the tariff, it operates as a premium. The navigation bounties are at the rate of .35 lire (about 12½ cents) per net ton per 1,000 miles on all long distance voyages. The total amount paid averages about 4,000,000 lire a year. Most of the long mail routes are maintained under special contract rather than under the general act.

Austria has a combined system of mail contracts with navigation bounties. Norway and Sweden have no direct subsidies, and their postal contracts are trifling in amount.

A. T. HAMLEY.

Substance [from Lat. *substantia* (noun, under a story, stand), constructed first as translation of Gr. *ὑπόστασις*, support, real essence, substance; *ὑπό*, under + *ὑστάναι*, stand; in philosophy, a term which appears first in Aristotle, who uses it in two senses, between which it has wavered ever since. Logically, it is the first of the categories as opposed to the other nine, which are its accidents (*κατηγορηματά*). There are first and second essences, the first always designating singular—e. g. a man, a horse; the second being general terms, as man, horse (Categ. V.). It is also used in the sense of *esse* or constituting essence, in which acceptance it is sometimes rendered into Latin by *essentia* (Metaph. IV. 8). The logical *substantia* is the first of induction (*ἐπίστασις*); the metaphysical *substantia*, the first of deduction (*ἐπίστασις*). None of the post-Aristotelian philosophical schools had profoundly enough to require the category of substance until the rise of the Neo-Platonists, who re-established it. Plotinus criticizes Aristotle rather severely for not distinguishing between material and spiritual substance (*Εἰσαγωγή*, bk. vi.), as he himself did. Porphyry and Simplicius accepted the Aristotelian doctrine. In the Middle Ages the metaphysical view prevailed, and substance was identified variously with God, person, etc. The same is true of modern times, dating from Descartes. He regarded substance as that which can exist independently of anything else, and Spinoza (*Ethics*, i. def. (iii)) as "that which is in itself and is conceived by itself"—a definition which, of course, identifies it with God. Leibnitz identified with substance the monads. Locke looked upon substance as a mere imagined substratum, holding attributes together, but did not altogether deny its validity, as did Hume (*Human Nature*, pt. I, § 6). Kant classed substance in his Transcendental Table of the Concepts of the Understanding along with Cause and Community under the head of Relation, and

defined its scheme as the "permanence of the real in time" (*Critique of Pure Reason*, p. iii., Meiklejohn's translation). Hegel defines substance as the "absolute, as relation to itself" (*Logik*, pt. 2, p. 185, ed. 1834), and as "the unconditioned essence (*Wesen*) existing in and for itself as being immediate existence" (*Propädeutik*, p. 105). Mill and the English school mostly follow Locke. In the orthodox doctrine of the Trinity, substance is used of the essential unity of the Divine Being as distinct from the tripersonality.

THOMAS DAVIDSON.

Substitutions, Theory of: a recondite but most attractive branch of modern mathematics, which has placed the theory of algebraic equations on a new basis. A substitution is an operation which is conceived to interchange quantities or symbols among themselves, putting one in place of another, but taking none away, and adding no new ones. If we have an algebraic expression containing several symbols, say the roots of an algebraic equation, some substitutions may change the value of the expression and others may not. For example, in the expression $x + y - z$, an interchange of x and y makes no change of value, because $x + y = y + x$; but interchanging either of these quantities with z changes the value. An excellent treatise on the subject is that of Netto, of which an English translation from the German original has been made by Prof. Cole, of the University of Michigan, and published at Ann Arbor. The most exhaustive treatise is that of Jordan, of Paris, published in 1870.

S. NEWCOMB.

Succession [from Lat. *successio*, deriv. of *succedere*, *successum*, go under, follow after; *sub*, under + *cedere*, go]: in European law, a term which covers all cases where rights or obligations previously established are acquired or assumed by new parties. Where one acquires a right previously held by another, the jurist speaks of an active succession; where one takes the place of a debtor, they speak of the succession as passive. The ordinary transactions of life give rise only to special or "singular" successions. In case of death, however, the Roman law, and the majority of modern legislations provide that some person or persons shall step into the place of the deceased, acquiring, in principle, all his rights, and becoming answerable for all his obligations. These persons are the "heirs" (see *HÆRES*), and their succession is termed universal.

The heir or heirs may have been designated by the deceased. At Roman law this could be done only by testament. (See *WILL*.) Teutonic custom, however, permitted rights of inheritance to be created by contract also, and most of the modern German codes retain the Teutonic rule (so the Prussian and Saxon codes, the German draft code, and, with limitations, the Austrian code). In the French law, rights of inheritance can be created by antenuptial contracts, but by such contracts only.

In the absence of heirs designated by the deceased, the succession is determined by the law. Succession *ab intestato* may be based upon the family organization or upon consanguinity. The first principle would wholly exclude illegitimate children. The second would exclude succession between husband and wife, and between adoptive parents and children. The Roman law, in its latest development, represents a compromise between the two principles. The same is true of all modern European legislations. Illegitimate children have some rights of inheritance, not only from the mother and her relatives, but also (if "recognized") from the father. Husband and wife also have reciprocal rights of succession, but the exact position assigned to the surviving spouse differs in different legislations. The law of intestate succession is often modified in this point by the rules of matrimonial property. See *MARRIED WOMEN*.

In general, succession is determined by the degree of kinship, nearer relatives excluding the more remote. (For the different methods of reckoning degrees, see *CONSANGUINITY*.) It should be noted, however, that the degree of consanguinity is never wholly decisive. In every legal system direct descendants, though of remoter degree, are preferred to ascendants and collaterals; and even among collaterals the remoter relative may be preferred—e. g. a brother's grandchild will always take precedence of an uncle, although by either the Roman or the canonical computation the latter is one degree nearer. In other words, every legal system regards the *kind* of relationship as well as the degree, and divides the relatives into classes, so that any member of a prior class excludes all members of a posterior class. Such a classification becomes perfectly logical only when succession

is avowedly based on the preference of the nearer *parentela*. This term designates the descendants of one ancestor. The *parentela* system divides all the relations of a deceased person into a series of such ancestral groups. The direct descendants of the deceased constitute the first *parentela*. His parents and their other descendants (i. e. his brothers, sisters, nephews, nieces, etc.) make up the second *parentela*. His grandparents and their descendants (not already included in the first or second group) are of the third *parentela*, and so on. As long as any member of a nearer *parentela* is in existence, all members of other *parentela* are shut out. This is claimed to be the Teutonic principle of succession. It lies at the basis of the English law of succession to real property. It is logically carried out in the Austrian code and in the codes of several Swiss cantons. It is adopted in the German draft code.

Whenever, under any system of succession, there are several heirs of the same class, those nearer in degree are preferred. This principle is modified, however, by the right of "representation," by which more remote relatives may be put into the place of their ancestor, and take the share to which he would be entitled if he had survived the intestate. In such a case succession within the class is said to be *per stirpes*, by lines. (See *DESCENT*.) In all modern legislation direct descendants take *per stirpes*; and the same system obtains, to some extent at least, among collaterals. Among remoter collaterals, however, the right of representation is frequently refused, because it tends to an undesirable subdivision of property.

Teutonic law never developed a "universal succession." It always recognized distinct succession to realty and to personality. It often drew further distinctions. It exhibited, in particular, a tendency to consider the channel through which property had come to the deceased; to prefer the paternal relatives when the property had been inherited from the father, the maternal when it had come from the mother. Modern European codes generally reject this distinction.

Special variations in the law of succession, which have existed in past times and still exist sporadically, are the exclusion of females or of the descendants of females (older Roman law), or a preference of the male line (classical Roman law). Similar tendencies reveal themselves in the older Teutonic law of real property; and under the influence of feudalism the preference of males was associated with the preference of the eldest son. (See *PRIMOGENITURE*.) In the succession to German peasant estates, also, the system of primogeniture generally obtained through the Middle Ages, and still obtains in some territories. Sporadically, a preference of the youngest son has also existed.

At Roman law the estate of a deceased person did not devolve *ipso jure* upon the heir unless he was a child or slave of the deceased. All others had to "enter," and could refuse to enter. The Teutonic principle, on the contrary, is that death vests seizin (at least as regards real property)—i. e. the legal heir acquires *ipso jure*. This rule is recognized in the French code and in the German draft code (in the latter for testamentary as well as intestate heirs); but the heir may divest himself of the inheritance by an express renunciation.

Since the acquisition of an inheritance makes the heir personally liable for the debts of the deceased, the Roman law established the rule, first for the children and then for other heirs, that they might take with the "benefit of inventory," in which case their liability was limited to the amount of the assets. This rule obtains generally in modern Europe. Conversely, when the heir is insolvent, the creditors of the estate may demand a separation.

See Demolombe, *Des Successions* (Paris, 1880); Koeppen, *Erbrecht* (Würzburg, 1888), and *Motive zum deutschen bürgerlichen Gesetzbuch* (vol. v., Berlin, 1888).

MUNROE SMITH.

SUCCESSION, in the common-law system, is employed in a more limited sense than in the civil law. In England and the U. S. the term is used only to describe the transmission of property (a) from a person or group of persons composing a corporation to his or their successors; or (b) upon the death of a person to his heir, devisee, or next of kin. Technically, it is only in the former sense—as describing the persistence of the rights of a corporation through all changes in its membership—that the term has any footing in the common law. The power of perpetual succession is one of the peculiar properties of a corporation, and the term successor, applied to a person in his corporate capacity, is the legal

equivalent of the term heir, applied to a person in his natural capacity.

In the other sense mentioned, however, the term *succession* is sometimes, by analogy with its signification in the civil law, employed to describe the acquisition of property rights upon and in consequence of the death of the former owner. Thus used it may comprehend the transmission of property by will or by descent, and it is under the description of these terms respectively that the devolution of property upon the death of the owner is treated by the common law. The subject of succession by testament is considered under the title WILL. "Descent," in its more general acceptation, includes the devolution, in case of intestacy, of personal as well as of real property. As only the latter is considered under that head, however (see DESCENT), the transmission of personal estate under those circumstances is considered here.

There was no such thing as a universal succession at the common law. This familiar principle of the civil law is not to be found in the early Teutonic customary law, nor did it ever find a place in the English system. The functions of the Roman *heredes* were from an early period divided up between the "heir," who took the real property, and the person or persons to whom the personal property descended; and it is not the English heir, but the personal representative—the executor or administrator—of a decedent, whose position bears the closest analogy to that of the Roman heir.

Although the right to dispose of personal property by will has always existed at common law, it was in the early history of English law much restricted by considerations of public policy, and of what were regarded as the rightful claims of the surviving members of the family. A rule of "reasonable partition," as it was called, prevailed, which provided that if a man left a wife and children surviving, one-third of his personal estate should go to the wife and one-third to the children, leaving only one-third of the whole to be disposed of by the will of the decedent. If the testator left a wife, but no children, or if he died a widower, but leaving children, he was entitled to dispose of one half of the estate, the other half to go to the surviving wife or children, as the case might be. Long before the time of Blackstone, however, this compulsory feature of the law of descent of personal property had disappeared, and the law was confined in its operation to cases where the owner of the estate died wholly or partially intestate.

There being no absolute right of succession to personal property recognized by the common law, except as above described, the title to all such property as a decedent might have disposed of by will, but which he failed so to dispose of, vested in the crown. By a series of early statutes this right of the crown was speedily reduced to a right of *ADMINISTRATION* (q. v.); the property being "distributed very justly to the wife and children and relations, to every one according to the degree that belongs to him" (Stat. Caserte, cap. 71). So a statute of William the Conqueror (cap. 84) provided that if a man died without a will, his children should divide the inheritance equally. In the course of time this right of administration became vested in the Church, and it continued to be exercised by the ecclesiastical tribunals in England from before the reign of Edward I. (A. D. 1272) down to the year 1857. It seems, from the authorities, to be clear that by an abuse of this right of administration the clergy claimed, and for a considerable period exercised the right to appropriate the personal property which thus came into their hands in case of intestacy to "charitable and pious uses," but when they were constrained by statute (31 Edw. III., Stat. I., cap. 11) to grant administration to the next of kin of the intestate (the just distribution to the nearest relations which the law contemplated was again made possible).

The distribution of intestate estates which now prevails dates back directly to a statute enacted in the year 1670 (29 and 30 Car. II., cap. 10) by which the respective rights of wife, children, and next of kin were fairly and, as the event has proved, permanently adjusted. By that statute one-third of the personal estate undisposed of by will, and remaining after the payment of debts and funeral expenses, was to go to the widow, and the residue to the children, to be equally divided among them. If there was no widow, the children took the whole of the surplus; if there was a widow but no children, the widow took one half and the next of kin (parents, brothers and sisters, grandparents, etc.), every one according to the degree that belongs to him, took the other half. If the intestate left no widow or children, the next of kin were entitled to the whole sur-

plus. In case a person entitled was dead, his legal representative would take his share. There was no discrimination (as there was in the rules regulating the descent of real property) against kin of the half-blood nor against female kin, but all of the same class or grade of kinship inherited equally. The rights of the husband in the personal estate of his wife were not altered by this statute, but remained as at common law. As a married woman could own no personal property during her life, she could of course leave none at her death, save only such claims against others (*choses in action*) as her husband had not previously reduced to possession. As in those, he was solely entitled to administration for the purpose of collecting them in and converting them to his own use. See MAXWELL WHEAT (Property Rights).

The statutes of distribution now in force in Great Britain and the U. S. are substantially only re-enactments of the act of Charles II. above described. (See, for example, New York Revised Statutes, II., 90, § 75, and Laws 1845, chap. 280.) In those States in which the common-law disabilities of the married woman have been removed and she has been rendered capable of holding property free from her husband's control, the rights of the latter with respect to the property left by the wife *as intestate* have also generally been somewhat modified. Thus it is provided by statute in New York that the husband of a deceased married woman who leaves descendants her surviving, shall be entitled only to such distributive share in the personal estate of his wife as a widow is entitled to in the estate of her husband. (Laws 1867, chap. 782, § 11.) This statute does not, of course, affect the rights of her husband in case the wife dies leaving no descendants. He is not required to share the estate with her next of kin, but takes the whole surplus as at common law.

The meaning of the expression "next of kin" and the relative rank of such persons, and the order of their succession, are defined with precision in the several statutes of distribution to which reference has been made. The test usually applied is nearness in degree of blood, and the method employed to ascertain the degree is usually that of the civil law. (See COGNATIVITY.) Persons born out of lawful wedlock have no part in the distribution of personal estate, whether they claim as children of the intestate or as next of kin. A bastard is *nobilis filius* by the common law, and is wholly outside the pale of consanguinity. In some of the States, however, an illegitimate child has by statute been rendered capable of inheriting from his mother. Of course, if such a person marries, he or she thereby becomes capable of taking property by descent from the wife or husband, the capacity in that case being wholly independent of any relationship of blood.

See the articles on DESCENT and HEIR. Consult also Stephen's *Commentaries*; Kent's *Commentaries*; *The American and English Encyclopedia of Law*, title *Intestate Laws*; Williams on *Executors*; Wharton on *The American Law of Administration*; and the statutes of the several States.

GEORGE W. KIRCHWAY.

Succession Wars: in general, wars resulting from conflicting claims to the throne. The term is especially applied to the four wars of the eighteenth century that arose from the disputed succession to (1) the throne of Spain (1701-14); (2) that of Poland (1733-35); (3) that of Austria (1741-45); and (4) that of Bavaria (1778-79)—of which only the first and third are of sufficient importance to be treated within the limits of the present article.

War of the Spanish Succession.—The weak and ineffectual King of Spain, Charles II. (1665-1700), had no children, and the succession accordingly devolved upon the collateral heirs. In the lifetime of Charles there were three principal claimants, first, Louis XIV., in right of his wife, Maria Theresa, daughter of Philip IV., who, however, had expressly renounced her right in the Treaty of the Pyrenees; second, Leopold I., Emperor of Germany, by virtue of his descent from Philip III. of Spain; and third, Joseph Ferdinand, the electoral Prince of Bavaria, grandson of Leopold and Margaret Theresa, the younger daughter of Philip IV. Neither Louis nor Leopold ventured to claim the throne for himself, but only for a member of his family, the former supporting the candidacy of his grandson, Philip, Duke of Anjou, the latter that of his second son, the Archduke Charles. Nevertheless, so great an accession of power to either the Bourbon or the Hapsburg dynasty was thought to endanger the independence of other nations, and it was finally agreed that the electoral prince should succeed to the Spanish throne

His death, however, in 1699, reopened the question, now further complicated by the fact that there was no third candidate on whom all could agree. In the intrigues which ensued Louis was successful, and Charles II., just before his death in Nov., 1700, made a will bequeathing all his possessions to Philip of Anjou. The latter was well received in Spain, and his title was generally recognized throughout Europe, but Louis took a course that was at once aggressive and impolitic. He alienated the other nations by declaring that Philip's succession to the Spanish throne had in no wise affected his right to the throne of France, and he angered England by pronouncing the Pretender the lawful heir to the English throne. In the winter of 1701-02 the Grand Alliance was concluded between England, the emperor, the Dutch, the King of Prussia, and the Grand Duke of Hesse, with the object of breaking the power of the Franco-Spanish monarchy. For ten years the war was actively carried on, the chief campaigns being in Spain, in Italy, in the Rhine countries, and in the Spanish Netherlands. In Spain the French were generally successful, and, first under Berwick and afterward under Vendôme, expelled the invaders and maintained Philip on the throne. In Northern Italy the Austrians, under Prince Eugene, conquered Milan and Mantua, and finally, after a victory at Turin, forced the French to withdraw altogether from Italy. In the meanwhile Marlborough and Prince Eugene had won the important victory of *BLENHENIM* (*q. v.*) in 1704. Marlborough's victory at Ramillies, two years later, drove the French out of the Netherlands, and their attempts to regain their lost footing were foiled by Marlborough and Prince Eugene at Oudenarde (1708) and Malplaquet (1709). Louis now sued for peace, but the terms imposed by the allies were so humiliating that he preferred to continue the war. Circumstances soon came to the rescue of France: the death of Leopold I. and of his son and successor, Joseph I., brought the Archduke Charles to the throne. To unite the thrones of Spain and the German empire seemed even more menacing to the balance of power than to maintain the Bourbon king in Spain. In England the Tories, who had supplanted the Whigs, desired peace, and in 1713 was signed the Treaty of Utrecht, stipulating that the two lines of the Bourbon house should renounce all claims of inheriting from each other, and the two crowns should never be held by the same person. In the following year the treaties of Rastadt and Baden settled the particular questions at issue between Austria and France.

The War of the Austrian Succession.—As the Emperor Charles VI. had no male heirs, he tried to obtain the accession of all the powers concerned to the Pragmatic Sanction, by which it was stipulated that after his death all the Austrian possessions should be transmitted undivided to his eldest daughter, Maria Theresa. The nearest claimant to the Austrian inheritance, the Elector of Bavaria, Charles Albert, never gave his consent to the Pragmatic Sanction, and when Charles VI. died (Oct. 20, 1740) a general desire was manifested among the other European powers to break up the Austrian state and divide its dominions. Claims were advanced by Spain, Augustus III. of Poland and Saxony, the King of Sardinia, and Frederick the Great of Prussia, to whom France was added by her traditional hatred of the Hapsburgs. Great Britain alone went to the aid of Austria. The Elector of Bavaria took possession of Bohemia in 1741, and in the following year was crowned emperor. Frederick the Great had in the meanwhile seized Silesia. Stripped of her provinces and threatened with an advance of the Bavarian and French troops upon her capital, Maria Theresa appealed to her Hungarian subjects for aid. It was granted, and a large army was soon in the field. A period of Austrian success followed, due in part to the purchase of Prussian neutrality by the surrender of Silesia to Frederick the Great; but the latter, alarmed by the continued success of the Austrians, again took the field in support of the emperor (1744). At the same time a reverse took place in the Austrian fortunes at other points of the contest. In Upper Italy a French army joined the Spanish, and fought with great success, and in the Netherlands Marshal Saxe began his brilliant campaign with the victory at Fontenoy May 11, 1745. Soon, however, events occurred which gradually prepared people's minds for peace. On Jan. 20, 1745, the emperor, Charles VII., died, and in September, Joseph, the husband of Maria Theresa, was elected Emperor of Germany under the name of Francis I. Frederick the Great had become thoroughly disgusted with his allies, the French, and in the death of Charles VII. he found an opportunity of retiring from the

coalition; peace was concluded between Prussia and Austria on Dec. 25, 1745. The war with France continued. Marshal Saxe gained brilliant victories in the Netherlands (at *Raucoux* Oct. 11, 1746; at *Laufeldt* July 2, 1747) and penetrated into Holland, where he took *Bergen-op-Zoom* and *Maestricht*. The British, however, had nearly destroyed the French shipping and conquered many French colonies, and when Russia, in June, 1747, joined Austria and sent an auxiliary army to Germany, France was willing to make peace. Peace was concluded at *Aix-la-Chapelle* in Oct., 1748. Austria gave up Parma, Guastalla, and Piacenza to Don Philip, of the Spanish Bourbon line, several districts of Milan to Sardinia, and confirmed Frederick II. in the possession of Silesia.

F. M. COLBY.

Succinic Acid [*succinic* is from Lat. *succinum*, *succinum*, amber, deriv. of *sucus*, *sucus*, juice]: one of the series of acids of which oxalic acid is the first member. Its composition is $C_4H_4O_4$. Succinic acid was known to the ancients as volatile salt of amber, from which it is obtainable by distillation. It is found ready formed in several plants, and even in animal bodies. It has been identified in the urine of dogs and rabbits. It is formed, with *SUBERIC ACID* (*q. v.*) and others of this homologous series, by the action of nitric acid on fatty substances. Pasteur found that it is an invariable product of the alcoholic fermentation of saccharine liquids. Many other organic transformations engender it. It is found in the watery part of the products of the distillation of amber, in solution, and crystallizes out by cooling. Warming with nitric acid will destroy the impurities, and enable pure succinic acid to be obtained by recrystallization. It is, however, obtainable much more cheaply from crude calcic malate, prepared from mountain-ash berries. This is fermented with yeast or rotten cheese, and the calcic succinate formed decomposed by sulphuric acid. Succinic acid crystallizes well, and is soluble in five parts of cold water. It melts at $356^\circ F.$, and boils at $455^\circ F.$, and is decomposed with formation of water and succinic anhydride, $C_4H_2O_3$.

Succory: See *CHICORY*.

Suc'coth (tents or booths): the Hebrew name of the second station in the Exodus itinerary (Ex. xii. 37, xiii. 20; Num. xxxiii. 5, 6). Excavations made by Naville in 1883, at Tell el-Maskhuta near the eastern end of the Wadi Tûmilât in the eastern Delta region of Egypt, and just westerly of the middle of the Isthmus of Suez, resulted in the discovery of a place which bore the civil or political name *Theku-t* (Succoth), the religious or sacred name *Pi-Tum* (PITHOM, *q. v.*), the Greek name *HEROÏPOLIS* (*q. v.*), and the Latin name *Ero-Castra*. The importance of the discovery was in the confirmation of the record of the building of Pithom as one of the "store cities" (Ex. i. 11) constructed for Ramses II., the Pharaoh of the oppression (thus approximately fixing the date of the Exodus), and in the determination of the starting-point and of the route followed by the Israelites when they left Egypt. See also *MIGDOL*. C. R. G.

Suchet, sū'chā', Louis GABRIEL, Duke of Albufera: soldier; b. in Lyons, France, Mar. 2, 1770. Entering the army in 1792, he served under Bonaparte, Brune, Masséna, Jourdan, and Moreau in the campaigns in Italy and Switzerland, passing through the grades from *chef de bataillon* (major) to that of lieutenant-general before the age of thirty. Subsequently he distinguished himself at Ulm, Jena, and Austerlitz. Under orders of Lannes he served with the Fifth Corps at the siege of Saragossa, and was designated by him to Napoleon on his departure for the command in Aragon. A series of battles and sieges (of Lérida, Mequinenza, Tortosa, Tarragona) gained for him the marshal's baton (July 8, 1811), and after the battle of Albufera and the siege and capture of Valencia he was created Duc d'Albufera (Jan. 24, 1812). He immediately joined Napoleon on his return from Elba. Under the Restoration he lived for several years in retirement, but was again invited to the court in 1819. The *Mémoires du Maréchal Suchet sur ses Campagnes en Espagne* forms one of the classics of military literature. D. in Marseilles, Jan. 3, 1826.

Suchow, or **Soo-chow-foo**: a city of China, capital of a department of the same name, and of the province of Kiangsu; situated on the Grand Canal, 80 miles W. of Shanghai (see map of China, ref. 6-K). The city is rectangular in plan, with walls 30 feet high and 12 miles in circuit. Outside five of the six gates by which the walls are pierced are large suburbs. The original plan, engraved in stone,

have been preserved since 1847 in the temple dedicated to Kwan-yin. In 1861 the Taipings reduced the city almost to a heap of ruins, the only buildings which escaped destruction being the temples 600 in number and pagodas, of which there are seven, one of them, the Great Pagoda, being the highest in China. Suchow is a great commercial and manufacturing city, thousands of looms turning out many varieties of silk and satin, and there are numerous workers in wood, iron, brass, tin, stone, silver, and gold. Its streets—7 or 8 feet wide—are too narrow for much traffic, but a great network of canals extends throughout the city and surrounding region, and along these all the heavy traffic passes. Though devoid of Western improvements, Suchow lies, from an Eastern standpoint, many marks of culture and refinement, and the quiet and elegance of life and manners enable it to be called the Paris of China. With Hangchow (q. v.) it shares the distinction of being likened by the natives to an earthly paradise. Pop. 500,000. A history of Suchow in 100 vols. was written 1,000 years ago. See six articles, by Rev. A. P. Parker, in vol. six of *The Chinese Recorder*.

THOMAS A. HAYES.

Sucker: any one of several fishes which have no resemblance to each other except that they "suck" in some way. 1. The *Catostomus* (q. v.). 2. The *Forsteryi* (q. v.). 3. Representatives of the families *Cyprinodontidae*, *Lipariidae*, and *Gobiinidae*. These have ventral fins peculiarly modified and adapted for adhering to rocks and other bodies. The species are numerous, and each family is represented on the coast of the U. S. Revised by F. A. Lucas.

Suckling, Sir John: poet; b. at Whitton, Middlesex, England, in 1699; educated at Trinity College, Cambridge. In 1717-18 he served as a volunteer under Gustavus Adolphus, King of Sweden, who was waging war against the Emperor of Germany. Returning to England, he was attached to the court of Charles I., and in 1680 equipped a troop of horse for the royal service against the Scotch. In 1640 he was elected to the Long Parliament, but was obliged to flee to France in consequence of his complicity in a plot to rescue the Earl of Strafford from the Tower. His works, most of them first published after his death, include four plays, some letters, *An Account of Religion by Reason*, and a number of songs, of which *A Ballad upon a Wedding* and *Way to Pile and Wan, Good Lover*, are still popular, and are admirable specimens of the gay and graceful poetry of the Cavaliers. A complete edition of his poems, plays, and romances was published in 1874. D. in Paris about 1642.

Revised by H. A. BEYER.

Sucre, see *krö*, more commonly called *Chuquisaca*, chook-suck-ka, and formerly *La Plata*: the official capital of Bolivia and capital of the department of Chuquisaca; on a terrace of the Eastern Cordillera of the Andes, overlooking the valley of the upper Pilcomayo, and in the midst of magnificent mountain scenery, 8,840 feet above the sea (see map of South America, ref. 6-D). It was founded by order of Pizarro in 1539, on the site of the Indian village of Chuquisaca (golden bridge), and during the colonial period was renowned for its riches, derived from the silver mines of the vicinity. Later, the Potosí mines attracted part of the population; but La Plata, as it was then called, remained the metropolis of the district. From 1559 it was the seat of the *audiencia* of Charcas, and hence the capital of Upper Peru, now Bolivia. After independence was won, in 1825, the name was changed to Sucre, in honor of the first president. It remained the official capital, but during the civil wars it became customary for congress to meet at La Paz, which is now virtually the capital of Bolivia. Remains of its former grandeur are seen in the fine cathedral and other public buildings. It has a university, the oldest in the republic, and is still the metropolis of the mining region and of a rich agricultural district. A railway to Oruro is projected. Pop. about 35,000. HERBERT H. SMITH.

Sucre, Antonio José, de: general; b. at Canana, Venezuela, Feb. 3, 1795. He joined the revolutionary army in 1817, served with distinction under Miranda and Piar, was on the staff of Bolívar's army, and rose to be general of division. He commanded the advance in the movement on Guayaquil, and his victory at Pichincha, May 24, 1822, finally drove the Spaniards from Quito or Ecuador. In the Peruvian campaign he took a leading part. After the battle of Junco, Bolívar left him in command of the army; and the decisive and brilliant victory of Ayacucho, Dec. 9, 1824, gradually ended the South American war for independence. In honor of this event he was created grand-marshal

of Ayacucho. In 1825 he was elected first president of Bolivia, and he governed with wisdom and success; but in 1828 the faction opposed to Bolívar, having obtained power in Peru, demanded Sucre's removal. To prevent a civil war he resigned and went to Colombia, where Bolívar placed him in command of the army acting against Peru. He defeated the Peruvians at the battle of Giron, near Quenya, Feb. 26, 1828, and forced them to sue for peace. The same year he was president of the congress of Colombia. While returning to his home at Quito he was assassinated near Pasto, June 4, 1830. HERBERT H. SMITH.

Sudeto-ria: a group of *Protium*. See *Protium*.

Sudan', **Soudan**, or **Soudan** (Arabic, *Sūdān*, *al-sūdān*, or country of the blacks; geographic name for that part of Africa lying S. of and adjacent to the Sahara, and extending, roughly, from 5° N. lat. to 15° N. and from 10° W. lon. eastward to the Nile. This region is occupied by many peoples and many different states, and embraces the basins of the Niger, Lake Chad, and the Bahrel-Ghazal branch of the Nile, representing, respectively, Western, Central, and Eastern or Egyptian Sudan. The upper part of the basin of the Senegal is sometimes distinguished as the French Sudan. This, with the Kong country on the upper Niger, is mountainous, with elevated plateaus. Central Sudan is less elevated and generally level, but contains some high mountains (as Athabaka, 8,500 feet). French, Western, and Central Sudan are generally well wooded and watered, and of great agricultural capacity. The Egyptian Sudan is generally arid. The races occupying the Sudan are very varied, mostly Negroes, but also including Fulas, Turcoms, Arabs, and in the east Shams. See *SENEGAMBIA*, *NIGER*, *SAHARA*, *CHAD*, *DAHOMY*, *BAHREL-GHAZAL*, *NILE*, *SAHARA*, etc. See also the *Travels of Mungo Park*, *Vogel*, *Baikin*, *Barth*, *Bodilly*, *Schweinfurth*, *Nachtigal*, and *Leuz*. MAX W. HANSENSTADT.

Sudbury: town of Nipissing district, Ontario, Canada, junction of the Canadian Pacific Railway with its Sault Ste. Marie branch; 125 miles W. of Mattawa and 182 miles E. of the Sault (see map of Ontario, ref. 1-1). It is in the center of a rich copper and nickel mineral district. Branch lines of railway run out short distances to the more important mines. Pop. 500. M. W. H.

Su'dermann, Herman: dramatist and novelist; b. at Matzlen, East Prussia, Sept. 30, 1857; was a private teacher and journalist until he suddenly became famous by his drama *Die Ehe* (1890), which, on account of the clever and sentimental treatment of the social question, achieved a remarkable success, and which has since been translated into several European languages. His subsequent plays, *Sadomas Eude* (1891), *Die Heimat* (1893), and *Die Schmutzlinge* (1894), were less successful, and established the fact that their author had been greatly overestimated. He also wrote a number of novels and short stories, of which *Der Antikrist* (1890) is the best. JULIUS GORDL.

Sudeten-Gebirge, see *lät-ten-gē-ber-ge*: a range of mountains which separates Silesia from Moravia, and connects the Riesengebirge with the Carpathian Mountains. They are 2,000 or 3,000 feet high, covered with pine forests, rich in coal and metals, and form plateaus with single peaks, rather than continuous chasms.

Sue, st. MARIE JOSEPH ECHUÏ: novelist; b. in Paris, Dec. 10, 1804; studied medicine, and held a position as surgeon, first in the army, then in the navy, until 1829, when, having inherited a considerable fortune, he retired and devoted himself to literature. His first novels, *Kernuel le Pirate*, *Pick et Pock*, *Atar-Gull*, *La Salamandre*, *La Chasse au chat*, *La Vigne de Kout-Yen*, which appeared between 1831 and 1835, were inspired by Cooper, and inaugurated in France the novel of naval adventures. In *Chéri*, *Arthor*, *Le Marquis de Lefortière*, *Jean Cavalier* (4 vols.), *Thérèse Danvers*, *Lutèce*, *Le Capitaine*, from 1835 to 1838, he wrote the historic, melodramatic, and romantic vein. After 1840 he became frankly socialist, and celebrated the proletariat in his most famous and exceedingly popular novels, *Malkilda* (4 vols., 1841); *Les Mystères de Paris* (10 vols., 1842-43); *Le Juif Errant* (10 vols., 1844-45); *Martin* (12 vols., 1847); *Les Sept Nègres captifs* (16 vols., 1847-48); *Les Mystères du Peuple* (16 vols., 1849-50). Elected to the Legislative Assembly in 1850, he took his seat among the most extreme radicals. After the coup d'état he left France and settled at Annecy, in Savoy, where he died Aug. 3, 1867. He wrote about fifty volumes of novels not mentioned here.

Revised by A. G. CARRIAGE.

Suetonius (swē-tō-ni-ūs) **Tranquillus**, GAIUS: author; b. probably about the beginning of the reign of Vespasian, and employed for some time by the Emperor Hadrian as his *magister epistolarum*. The date of his death is unknown, perhaps about 160. His principal work, *Duodecim Caesarum Vitae*, has been preserved entire and in authentic form. It contains biographies of the first twelve Roman emperors, beginning with C. Julius Caesar and ending with Domitian. The best editions are by Baumgarten-Crusius (Leipzig, 1816), C. B. Hase (Paris, 1828), and Roth (Leipzig, 1858). The other writings are best given by Reifferscheid (Leipzig, 1860). English translations of the *Vitae*, by John Clark (London, 1732), and by Thomson and Forrester in Bohn's Classical Library (1855). Revised by M. WARREN.

Suevi, swē-vi: originally a collective name, comprising several individual Germanic tribes which formed a kind of union. It is thus used by Caesar and Tacitus. In the fourth century the name was applied to a single tribe, one branch of which settled in the regions along the Neckar, afterward called Suabia, while another branch broke into Gaul, and in 409 crossed the Pyrenees and penetrated into Spain, where they embraced Christianity, conquered Galicia, and formed a kingdom, which in 585 was united with the Visigothic empire.

Suez, soo-ēz': town of Egypt; at the head of the Gulf of Suez, an inlet of the Red Sea, in lat. 29° 59' N. and lon. 32° 31' E., and 2 miles from the southern end of the Suez Canal (see map of Africa, ref. 2-G). The surrounding region is a desert, and provisions and water must be brought to the town from a distance. Since the opening of the railway from Cairo to Suez, and the opening of the Suez Canal, the city has grown rapidly. Pop. (1882) 10,918; estimated (1895) 12,500. Revised by M. W. HARRINGTON.

Suez Canal: See SHIP-CANALS.

Suez, Gulf of: the western and larger of the branches into which the Red Sea divides lying between Egypt and the peninsula of Sinai. Its extreme length is about 180 miles; its average breadth 20 miles. It was known to the ancients as the Gulf of Heroöpolis, and the generally received scene of the passage of the Red Sea by the Israelites is near the present head of the gulf.

Suez, Isthmus of: a neck of land connecting the continents of Asia and Africa, and separating the Mediterranean from the Red Sea. Its extreme breadth from the Gulf of Suez to that of Pelusium is about 72 miles in a straight line, but following the course of the canal the distance is 100 miles. The surface is low and sandy, having an average elevation of not more than 6 or 8 feet above the sea, but in places reaching to 50 or 60 feet. In general, the isthmus is almost a desert; where irrigation has been practiced, however, it is quite fertile. It is probable that the whole isthmus was once covered by the waters of the Mediterranean and Red Seas, which were then connected.

Suffix: See STEM and ROOT.

Suffocation: See ASPHYXIA.

Suffolk: county of England; bounded N. by the Ouse, S. by the Stour, and E. by the North Sea; area, 1,475 sq. miles. The surface is flat, and the soil for the most part productive and excellently cultivated. Wheat, barley, beans, oats, and hemp are raised, dairy-farming is extensively carried on, and butter is one of the principal products of the county. Five members are returned to the House of Commons. Pop. (1891) 369,351. Capital, Bury St. Edmunds.

Suffolk: town; capital of Nansemond co., Va.; on the Nansemond river, and the Atl. and Danv., the Norf. and Car., the Norf. and W., the Seaboard Air Line, and the Suf. and Car. railways; 18 miles S. W. of Norfolk (for location, see map of Virginia, ref. 7-I). It is in an agricultural region; is engaged in lumbering, oyster-packing, and the manufacture of iron, lime, and woolen goods; and contains a State bank with capital of \$20,000, and a daily, a monthly, and 2 weekly newspapers. Pop. (1880) 1,963; (1890) 3,354.

Suffragan [from O. Fr. *suffragan* < Lat. *suffragans*, pres. partic. of *suffragari*, vote for, assist; cf. also Late Lat. *suffraganeus*, suffragan]: a bishop of a single diocese in an ecclesiastical province subject to the ecclesiastical authority of the metropolitan of that province. A coadjutor is sometimes said to be suffragan to his superior bishop. A bishop of a limited part of a diocese is a suffragan to the bishop of the diocese. For instance, the Bishop of Dover is a suffragan of the Archbishop of Canterbury, while all

bishops of the province of Canterbury are suffragans of the same metropolitan in a different sense. In the Protestant Episcopal Church in the U. S. suffragan bishops are not allowed, the canons forbidding their creation. All attempts to remove this prohibition have failed.

Revised by W. S. PERRY.

Suffrage: See CITIZEN and PRIVILEGE.

Sufis, or **Soofees**: the mystics of Islam, deriving their name from a coarse woolen cloak, their principal garment. Rabi'a, a Mussulman woman who lived not long after the prophet Mohammed, taught as her central doctrine divine love, and is reckoned by them their founder. Abu Saïd, one of Abul Khafr, in the ninth century, advanced further, and urged abandonment of the world and consecration to a contemplative life. The various doctrines developed by his adherents and followers embrace every possible phase of mysticism. Many are pantheists, and declare that God is all, but that all is not God. Some claim direct communication with the Deity, and a mysterious union or identification with him. They are numerous in Persia, and have furnished noted scholars and poets. See DERVISHES. E. A. GROSVENOR.

Sugar [M. Eng. *sugre*, from O. Fr. *sucre*, Ital. *zucchero*, from Arab. *sokkar*, from Sanskr. *ṣarkarā*, whence Gr. *σάκχαρος*, whence Lat. *saccharon*, whence Eng. *saccharine*]: any compound of a carbohydrate nature which is soluble in water. In the common acceptance of the word, it is any such compound having a sweet taste, but the term usually includes only cane-sugar (sucrose, or saccharose), and possibly also sugars made from starch, known as glucose or grape-sugar, and consisting chiefly of dextrose, dextrin, and maltose.

The sugar of commerce is derived almost exclusively from sugar-beets and sugar-cane, the former supplying a little less than two-thirds and the latter a little more than one-third of the world's consumption; sugar from either of these sources is usually called cane-sugar, although the more correct term is sucrose. The other sources of sugar, such as maple, palm, sorghum, and starch, while of importance for special purposes and in limited localities, do not supply sufficient quantities to affect sensibly the commerce of the world.

Occurrence.—Sugar is a normal product of almost every kind of vegetable growth. It is the first and principal result of the biochemical activity of all green plants, and is an important component of many plants devoid of chlorophyll, such as the mushroom. Its formation is the result of the condensation in the living plant-cells of its elements pre-existing in the air. These elements are carbon dioxide and water. The sugar thus formed furnishes the principal food-supply for the growth of all the other tissues of the plant. From it are formed directly the wood-fiber, the digestible fiber, the pentosans and the starches, all of which have essentially the same centesimal chemical composition. Indirectly, it enters into the formation of the fats and oils and of the nitrogenous constituents of the plant organism.

In many plants almost all the sugar produced is consumed in their further growth and development. In others the amount of sugar produced is far in excess of the demands of nutrition, and it is then stored as a waste or excess product in some part of the plant itself. In the sugar-cane, sorghum, and green Indian corn it is found in the stalks. In root-crops, such as beets and turnips, it is found in the fleshy roots. In trees, such as the maple and sugar-palm, it is dissolved by the first flowing sap of the spring. It exists in nearly all seeds, and of many, such as the coffee-bean, the peanut, and the cottonseed, it forms an important constituent. Sugar is also formed as a normal product of the functional activity of certain animal organs, such as the liver, and is an abnormal product of these in certain forms of disease, as diabetes mellitus. Many kinds of sugar have also been formed synthetically in the chemist's laboratory.

History.—(1) It is quite certain that the nations of remote antiquity were not acquainted with sugar as such, but honey was known to them all. The bees must be regarded as the first manufacturers of sugar. The sugar which is found in HONEY (*q. v.*) is derived chiefly from the nectar of flowers, and this nectar consists of mixtures of cane-sugar and a sugar made by the inversion thereof, known as invert sugar or fruit-sugar. The sugar of the nectar of flowers in its fresh state consists largely of pure cane-sugar, but this, in passing through the organism of the bee, becomes inverted probably by some indirect biochemical action or under the influence of the formic acid which the bee secretes. The result is that the honey which is stored by bees, and which they

soluble from the nectar of flowers, consists almost exclusively of invert sugar and water. The percentage of water varies largely, but the mean may be taken to be about 15 or 20.

The chief supply of sugar for consumption, for medicinal uses and as an article of luxury, was furnished by bees until probably the beginning of the fifteenth century.

(2) Sugar-cane, *Saccharum officinarum*, doubtless had its origin in India, and, from the best information which can be obtained, the original varieties contained only a very small quantity of sugar, probably not more than from 2 to 4 per cent. Its constant cultivation and selection the content of sugar in the sugar-cane has been increased until it averages from 10 to 12 per cent. in Louisiana, 15 per cent. in Cuba, and 16 per cent. in the Hawaiian Islands. It is believed that the original form no longer exists.

Cultivated sugar-cane will not return to the wild state, and is uniformly diseased when deprived of the care of man. From the earlier travelers Cook (1775) and Forster (1777), found in the Hawaiian Islands and other South Sea Islands only the cultivated cane. The statements which have been made regarding the existence of the wild varieties in Africa have not been positively negatived, but it is more than likely that these were some of the varieties of sorghum which grow wild in all these localities and resemble in many respects the sugar-cane, as were those described by Humboldt on the Indus, the Rappahannock, and the Persian Gulf. Henshaw, in 1860, declared that the banks of the mouth of the Mississippi were thickly covered with sugar-cane, which, under the heat of the sun, exuded sugar that dropped from the stalks like gum. This growth was doubtless the wild cane *Arundo donax* or *Arundinaria gigantea*, which, though also a grass, is very different from the sugar-cane.

While the cultivated cane will not revert to a wild state, yet with proper care, in favorable climates, it will continue to grow from the same stubble for fifteen or twenty years. In some cases it has been known to grow for forty years.

The sugar-cane does not appear to have been known outside of Bengal at the time of the writing of the Rig-Veda (about the fourteenth century a. c.). In other Vedas the sugar-cane is mentioned, especially in the Atharva-Veda; but even at the time of Buddha the sugar-cane was not generally known in that part of India. At that period the stalk was either used directly or the expressed juice drunk without further preparation. The first use of bry for concentrating sugar-juices was doubtless also due to the inhabitants of India; about 600 or 700 years a. c. From there

this art was spread among all nations of antiquity. Humboldt asserts that the Aztecs in Mexico were accustomed to make sugar from the stalks of maize before the Spanish invasion. At first only syrup or molasses was made, and after that the art of sugar-making was learned. Probably solid sugar was first made and used in India about the sixth century of the Christian era.

The existence of the sugar-cane was not known to the Greek nations before the Christian era. Pliny (23-79 a. d.) says sugar came from Arabia, but the Indian product was preferable. It was a honey collected from canes, white like gum, breaking easily between the teeth, and was used only as a medicine. It was not until about 500 a. d. that the knowledge of the art of growing and refining sugar began to spread westward. In their wars of conquest toward the East the Mohammedans first learned of the manufacture of sugar. At the time of Harun-al-Raschid the tribute of some of the conquered provinces was paid partly in sugar. It was valued as a luxury and as a medicine.

In the eighth century the culture of the sugar-cane had spread over the greater part of the Nile delta. The sugar-

Sugar-cane.

cane grew so well in Egypt that it soon became an article of export from that country to the Mohammedan Asiatic provinces. Because it could not well be transported by water, it was always sent overland and many of these cargoes fell into the hands of the Christians during the crusades, and in this way the knowledge of sugar was diffused throughout Europe. When Sicily was conquered by the Arabs the culture of sugar was introduced into that island from Egypt, and thence also to Spain at the time of the Moorish conquest in the eighth century. Sugar-cane is still cultivated in the valleys along the southern Mediterranean shore of Spain. In the ninth and tenth centuries the culture of sugar-cane in Spain was carried on in all of the provinces of Andalusia. In the beginning of the fifteenth century the Spanish production amounted annually to over 2,000,000 cwt., and there were fifteen sugar-factories at the village of Novell, near Granada.

At the time of Marco Polo, about 1290, the sugar-cane industry had assumed considerable importance in China, whence it spread to Siam, Ceylon, and Japan. The first introduction into Western Europe was made by the returning crusaders, by whom it was used only as a medicine. The sugar brought from Syria soon came into use as a delicacy, and in Paris of France as early as the twelfth century sugar became a regular article of commerce, being used for making cakes and preserving fruits. From France the use of sugar spread into Holland, Italy, and Germany. Venice, in the Middle Ages, became the headquarters of the industry, receiving the crude materials from the East, refining them, and delivering the products to the North and West.

Sugar is not mentioned in the oldest German literature, and it is first spoken of by the poets of the twelfth and thirteenth centuries. Later it became an article of commerce with the Venetian dealers and the German merchants at Constantinople. It was used in cakes and preserves and eaten only by the wealthy.

A considerable part of the sugar used in Europe in the fourteenth and fifteenth centuries came from Cyprus, where the culture of sugar-cane had been introduced by the Arabs in the seventh century. Perhaps the greatest quantity of sugar from any country among those mentioned was sent to Europe from Egypt.

The refining of sugar was probably first practiced at Venice; at least that is where the industry first assumed importance. In a directory of that city, published in 1475, refiners of sugar are mentioned. The art of refining, as at first practiced, consisted simply in melting the sugar in water and recrystallizing it by evaporation over an open fire. This was often repeated two or three times.

Columbus took sugar-cane from the Canary Islands to San Domingo at the time of his second voyage, and his report to the Spanish king told of the wonderful growth of the cane in the New World. A new lot was sent in 1506. From San Domingo the culture of sugar-cane spread to Cuba and the neighboring islands and also to Mexico. As early as 1553 Mexico exported sugar to Spain. In 1592 sugar-cane was introduced into Brazil from Madeira. Within 100 years after the first introduction of sugar-cane into the New World the production of sugar therein was so great as to turn the dealers of Europe toward the West for their supply of this commodity.

In 1597 a sugar-refinery was erected in Dresden, and soon afterward Antwerp became a center for the sugar-trade. In the seventeenth and eighteenth centuries the production of sugar rapidly increased in the New World, especially in the British and French colonies in the tropics, San Domingo leading with a production of 20,000 tons annually. The revolution of 1791 in that island, however, almost destroyed the industry.

The processes of manufacture in all these countries were of the most primitive kind. The canes were crushed in crude mills driven by men, wind, or water; clay and lime were largely used in purifying the juices, the clay acting chiefly in a mechanical way in removing impurities. The boiling was accomplished in iron or copper kettles over the open fire. The raw brown sugar thus made was refined by melting and recrystallizing, the white product obtained in this way being known as "king's sugar." Europe continued to be the only market for American sugars, and in the competition thus produced the sugar industries of Sicily, Egypt, and Spain were ruined and practically ceased to exist. The desolation wrought by the Thirty Years' war in Germany put a stop to the consumption of sugar in that country, and the commercial downfall of Spain and Venice threw the trade

of the world into the hands of Great Britain, France, and Holland. In Great Britain the consumption of sugar increased rapidly. In 1700 it was 10,000, in 1750 80,000, and in 1800 150,000 tons annually.

The first sugar made in Louisiana was in 1791 by Don Antonio Mendez, associated with a farmer named Solis. Étienne de Boré, about 1794, was the first to make sugar-culture a commercial success, and his first crop amounted to nearly 100,000 lb., for which he received about \$12,000. His plantation is now a part of the city of New Orleans. In 1818 Joseph Coyron erected the first steam-engine ever used to grind sugar-cane in Louisiana. The variety of cane in cultivation at first was known as creole, and was a very tender plant, easily injured by frost. In 1820 the red-ribbon cane, a much hardier variety, was introduced from Georgia. The yield of sugar gradually increased in Louisiana until 1853, after which it slightly decreased until 1861, when the largest crop ever made in the State up to that time was secured, viz., 230,000 tons. The civil war almost paralyzed the sugar industry in Louisiana, and for three years no data of yields are recorded. In 1864 the crop amounted to only 5,000 tons. From this time on the production of sugar in Louisiana increased, but not with regularity on account of disasters from flood and frost, until the season of 1893-94, when it amounted to 320,000 tons.

Sugar-cane is also cultivated to a considerable extent in Texas and Florida, and in a smaller way in Georgia, Alabama, and Mississippi.

3. The sugar-beet, *Beta vulgaris*, originally came from the lowlands of Burgundy, and was carried by the Mennonite exiles into the Palatinate. From this locality it gradually spread to all parts of Germany, and was grown as cattle-food. In 1747 Marggraf (1709-82) discovered that sugar could be obtained from the common beet. Achard (1753-1821), in Kaulsdorf, near Berlin, was the first who undertook a systematic culture of the beet, and he largely increased its content of sugar. In France the sugar-beet appeared soon after its introduction into Germany and Holland, and was cultivated by Vilmorin in 1775, but its first systematic culture there was undertaken by Abbé Rozier in 1782. In 1786 it was introduced into England by Perkins and in 1830 into the U. S. by Vaughn and Ronaldson. In 1798 Achard, in Berlin, succeeded in preparing crystallized sugar from beets in considerable quantities, and as much as 16 cwt. was used in 1800 in the bakeries of Berlin.

The first real beet-sugar factory was erected by Achard, with royal aid, at Kunern, in Silesia, and put in operation in Mar., 1802. Many attempts were made to manufacture beet-sugar in Germany during the decade beginning in 1800, but in spite of the fact that the competition with cane-sugar was practically removed by the Napoleonic embargoes these attempts were generally unsuccessful. In France the Emperor Napoleon appointed a commission to investigate Achard's work, and as a result an imperial decree, in the early part of his reign, established the beet-sugar industry in France, and a considerable subvention from the imperial treasury was accorded it. Two factories were built at St-Ouen and Chelles, but for lack of scientific supervision they failed of their purpose.

In 1808 Delessert undertook the culture of the sugar-beet at Passy, and by means of clarification with lime, sulphuric acid, and charcoal, succeeded in making a good merchantable sugar. In 1812 the Emperor Napoleon, as a result of a personal inspection at Passy, ordered that ten new factories be immediately constructed, and committed the work of construction to Delessert. In Great Britain, on account of her tropical colonies, the introduction of the beet-sugar industry was vigorously opposed, and its further development on the Continent discouraged.

In the U. S. attempts were made as early as 1830 by a Philadelphia company, of which John Vaughn and James Ronaldson were successively presidents, to introduce the culture of the sugar-beet. By reason of the absence of practical information little was accomplished. In 1839 a beet-sugar company was formed at Northampton, Mass., by David L. Child, and 1,300 lb. of sugar was made and the enterprise was then abandoned. The next company of which there is any account formed for the purpose of promoting the culture of the sugar-beet was in 1863, in Livingston co., Ill., but no practical results were obtained. In 1864 the Gennert Brothers established a beet-sugar factory at Chatsworth, Ill., but failed for lack of capital. The establishment was subsequently bought by a German company and removed to Freeport, Ill. All these attempts,

however, ended in failure. The next beet-sugar factory in the U. S. was established in 1866 at Fond du Lac, Wis., and for two or three years a considerable quantity of sugar was made at that point. In 1870 the proprietors removed to California and organized the Alvarado Sugar Company, which, after various vicissitudes, finally succeeded in establishing itself on a firm basis, and is still in operation. Companies were also organized for the manufacture of sugar from the sugar-beet at Sacramento, San José, and Soquel, but none of them except the Alvarado company was finally successful. In 1878 a large factory built on modern principles was established at Portland, Me., and in the following year factories were also established at Wilmington, Del., and Franklin, Mass., and large sums of money were invested therein. After unsuccessful attempts at profitable manufacture all of these establishments were abandoned. For many years no further attempts were made to manufacture beet-sugar in the U. S., except at Alvarado, Cal. In 1888 a factory was built at Watsonville, Cal., and in rapid succession factories were established at Grand Island and Norfolk, Neb., Chino, Cal., and Lehi, Utah. At present (1895) there are six fully established beet-sugar factories in the U. S. The total quantity of sugar manufactured at these localities during the season of 1893-94 amounted to 45,191,296 lb.

Palm-tree Sugar.—An old and, at one time, important sugar of commerce is the product of certain of the varieties of the palm-tree. It has been and is produced principally in India, where it is known as jaggery, a word which is of the same origin as the word sugar. The palms used for sugar-making are planted in rows in high and dry land, and can be used from five to thirty years. The trees are tapped in the same manner as the maple, but usually a small triangular hole is cut into the tree for the purpose of collecting the sap, which is removed by boring a hole into this receptacle from below and inserting therein a small bamboo cane, which conducts the sap into an earthenware receptacle. The sap flows principally during the night, and should be removed the following morning before the sun becomes very hot. After tapping, the tree will continue to afford a supply of sap for about three days, and must then be allowed a period of rest. The sugar season begins in November and lasts until the middle of February. The cooler and calmer the weather the better the harvest. The juice, with the addition of a little lime, is evaporated over the naked fire to a thick sirup. Part of it is sometimes further dried in the sun to a hard mass. This thick sirup is sometimes called date-tree honey, and was known as an article of commerce at the time of Herodotus and probably for many years before. The sugar of the palm as it comes from the tree is nearly pure sucrose, or cane-sugar, but much of it becomes inverted in the crude process of manufacture. Good palm-trees yield from 30 to 40 lb. of sugar in a season. The varieties cultivated are chiefly *Phoenix sylvestris*, *Cocos nucifera*, *Borassus flabelliformis*, *Caryota urens*, and *Arenga saccharifera*. A grove of from 600 to 800 palms is considered a valuable possession. The annual production in India is estimated at 1,000,000 metric centners (100,000 tons of 2,204½ lb.).

Maple-sugar.—The maple-tree is the sugar-palm of temperate climates. Of the several varieties of this tree, only the *Acer barbatum* (also called *A. saccharinum*) is used to any extent for sugar-making. The principal centers of the maple-sugar industry are in Vermont, New York, and Ohio, but almost everywhere in the northeastern parts of the U. S., and also in parts of Canada, some sugar and molasses are made. Only the old trees are used for sugar-making, and, until within a few years, the natural forests. Within the past few decades there has been some planting of maple-trees for sugar-producing purposes, although a grove is not profitable for use until it is thirty or forty years old. The best groves for sugar-making are those in which the underbrush and small trees have been cut away, allowing the larger trees an opportunity to increase their leaf and twig growth. As a rule, the shorter trees with dense spreading overgrowth are better for sugar-production, both in the sweetness and quantity of sap. Woodpeckers are quick to discover the sweeter trees, which they fill with holes in the springtime for the purpose of drinking the sap. The excess of sap flowing over the bark darkens it, and the sweeter trees thus often have almost a black exterior.

The sugar season begins after the breaking up of the winter. In the more southern latitudes the sap will flow freely after the first thaw in winter, often in January. In

Southern Indiana and Ohio the manufacturing season usually begins in February and lasts until the end of March; in Vermont in March, lasting until the end of April. A cold, steady winter is favorable to a good season, because it prevents the flow of sap until the sugar season fairly opens. The trees are tapped by boring with an auger, three-quarters of an inch in diameter, on the south-west exposure of the tree. The holes are bored at a distance of from 2 to 4 feet from the ground. Spiles made of chert-tubes or of metal are fitted into the sugar-holes, water-tight, so as to cause all the sap to flow out through the central orifices, where it is collected in appropriate vessels. Where little regard is had for the welfare of the tree a notch is cut in it as described for the date-palm. This is, however, very injurious, and trees thus treated during a series of years lose their vitality. From one boring the sap will continue to flow for a considerable time—usually for one season. Sometimes, however, a second boring is practiced to increase the flow. Usually two spiles are put into each tree; in small trees, sometimes only one; in very large ones, three or four. The flow of sap is most free during a warm, still day. It is checked by a frost at night and by high winds. In case of a thaw it will flow for twenty-four or even for forty-eight hours. It will then cease and begin again after another freeze. When the buds begin to swell later in the spring the flow ceases, and if started again by a subsequent freeze the sap is found to be less sweet and to have undergone a viscous fermentation which unfit it for sugar-making. The sap is nearly pure sugar and water, containing, however, certain organic aromatic compounds, which give the "maple flavor," and make both sugar and molasses so highly prized that they command double the price of similar sweets made from cane or other sources. The maple-sap also contains notable quantities of malic acid combined with lime. This is especially the case toward the end of the manufacturing season. In evaporating the sap the malic acid is precipitated, and forms a scale or sandy deposit in the bottom of the pans which is known as sugar-sand. The sap of the maple contains varying quantities of sugar, depending on the year, the time of collection, and the position and peculiarities of the trees.

In the analysis of the sap from twelve trees from a maple-bush in Northwestern Indiana, taken on Mar. 21, the average content of sucrose was found to be 2.98 per cent. The highest content in any one tree was found to be 3.43 per cent.; the lowest, 1.95 per cent. At the same time the sap from a tree in Southern Indiana showed 4.90 per cent. The average content of sugar in the sap of fifteen trees near Lumberton, Vt., examined daily from Apr. 7 to Apr. 28, was found to be 3.33, 3.72, 3.01, 3.66, 3.42, 3.13, 3.74, 2.98, 3.73, 3.33, 3.55, 3.69, 4.06, and 3.18 per cent. respectively.

From a comparison of all the analyses made it is apparent that the average percentage of sugar in the sap is about 3.5. In one instance determined in Vermont in the mixed sap of 3,350 trees, taken at intervals from Apr. 9 to 22 inclusive, the average percentage of sucrose was found to be 3.25. The average yield of sugar from a tree is difficult to determine, inasmuch as the sap of the trees is mixed and no attempt made to keep the samples separate. In some few instances it is stated that trees have yielded as high as 40 lb., and yields of 20 lb. per tree are not uncommon. The average quantity of sap required to make a pound is 16 quarts. It is probable that the average yield of all the trees during one season and from one season to another is about 3 lb.

In the best orchards metallic spouts are used strong enough to hold a pail. The pails are preferred to wooden ones, the latter often imparting a bad taste to the sap. The sap is collected from the pails as often as possible, and when drawn to the small factory it should be strained before being placed in the storage-tanks. For boiling, the best sugar-makers use pans made of Roosts iron, about 5 feet long, 2-3 feet wide, and 8 inches deep. They are set on arches of brick 20 inches in depth and provided with grate bars and other appliances to make the use of fuel economical. Open kettles are also often employed, but not by the best makers. In many factories the juice before entering the evaporator is passed through a heater, a copper box provided with tubes, through which the waste heat from the furnace passes. Many of the makers also use the continuous evaporating pans so largely employed in the manufacture of sorghum molasses. The fuel usually consists of the waste wood from the grove itself or adjoining forests. From 1 to 125 cords of wood are required for each 100 lb. of sugar produced. Sometimes the white of eggs is used for clarifying the sap, but as a rule this

is not necessary. The scums which form during the boiling and which are usually of a very dark color, should be carefully removed. They contain large quantities of albuminous matters which if left in the sugar or syrup impair their keeping qualities. The sugar is either poured while hot into moulds, or, if a granular variety is desired, is vigorously stirred while cooling. This process is termed "sugaring off." The granular sugar thus made, especially while fresh, has a most delicious flavor and is highly prized. The retaining of maple-sugar would deprive it of its characteristic flavor and thus reduce it to value to the level of ordinary sugar. It is therefore never practiced.

The quantity of maple-sugar made in the U. S. is not easily ascertained. Much of it goes into domestic use, while other large quantities which are placed on the market are adulterated. The total quantity varies probably between 15,000 and 20,000 tons per year. There is little evidence of either an increase or a decrease in the amount, but inasmuch as the maple-tree tends to grow naturally in rich soils, there is a disposition on the part of the farmers to clear the land and thus to diminish the output of sugar. The maple forests which are best preserved therefore are those which are found growing on places too hilly or rough for easy tillage.

Attempts were once made to introduce the growth of the maple-tree and the manufacture of sugar therefrom into Europe, but without any encouraging results. Maple-sap was sent to Berlin from the U. S. in 1797 at the instance of a member of the Prussian cabinet, and encouragement was given to use also the sap of the silver maple, already growing in that country, for sugar-making purposes. Some little sugar was made in this way during the decade and a half beginning with the nineteenth century. The reopening of the West Indies to European commerce, however, which attended the downfall of Napoleon, caused all these efforts to cease, and the production of maple-sugar became confined to North America.

Maize-stalks.—The stalks of maize, *Zea Mays*, at the time of the formation of the starch in the grain are filled with a sap very rich both in sucrose and reducing sugars (sugars which reduce an alkaline copper solution with the formation of suboxide of copper). Humboldt reported in the account of his visit to Mexico that, before the arrival of the Europeans, the Mexicans as well as the Peruvians pressed out the sap of the maize-stalks, and by concentration thereof prepared sugar, and Cortés reported to Charles V. that the Mexicans had for sale honey, wax, sirup, and sugar from the maize-stalks, which were as sweet as sugar-cane. The maize used was doubtless sweet corn, the juice of which will sometimes yield as much as 16 per cent. of sucrose. From maize grown in Germany in 1760 Just obtained a fairly good sugar, and in Italy, in 1784, Jaspoin and Marabelli erected a mill for pressing the maize-stalks, and succeeded in making sugar therefrom.

Numerous analyses of the juice of maize-stalks were made in the U. S. Department of Agriculture from 1878 to 1882, and attempts were made on a small scale in the manufacture of sugar. Previous to this, in 1870, F. L. Stewart had announced in *The Public Ledger of Philadelphia* the result of some of his experiments in manufacturing sugar from maize-stalks. According to his analyses the juice of the maize-stalks contained 10.8 per cent. of sugar. In 1876, in the Department of Agriculture, samples of maize juices were analyzed showing 5.6 and 6.7 per cent. respectively of sucrose in the juices. In 1881 analyses of a large number of samples of maize juices showed a percentage of cane-sugar varying from 9 to 15, and in 1880 nearly 800 analyses were made showing a variation of cane-sugar in the juices from 9 to 15. The percentage of reducing sugars in the juices was also determined, showing a wide range in total numbers of from 1 to 4 per cent.

The attempts at making sugar, however, from these juices were attended with very little success, the syrups resulting from concentrating them crystallizing with great difficulty. Nevertheless a committee of the National Academy of Sciences reported that the experiments had shown that in successive years there was obtained from the stalks of common maize, after the ripened grain had been plucked, sugar at the rate of 900 lb. per acre.

Although the stalks of maize at the time the starch is in a milky state in the grains contain large quantities of sugar, there is no reason whatever to believe that maize can ever enter into competition with the sugar-cane and the sugar-beet as a source of commercial sugar. In a small way and for domestic consumption a fairly good sirup may be made

therefrom, but all enthusiastic promoters of enterprises for making sugar from maize-stalks should be reminded that economically the task is a hopeless one so long as cheaper and better sources of raw material are available in practically inexhaustible supplies.

Sorghum Sugar.—The history and method of making sugar from sorghum are described in the article *SORGHUM* (q. v.).

Culture of Sugar-cane.—Since the sugar-cane and sugar-beet are practically the sources of all commercial sugar, a description of the methods of cultivation will be confined to these two plants. Sugar-cane is propagated by cuttings, and in rare instances from the seed. All parts of the cane having well-formed joints may be used for planting. In some localities it is customary to cut off the top, which is less rich in sugar, and use it for planting, while the rest is employed for sugar-making. The more common practice, however, is to use the whole cane, with the exception of that portion of the top devoid of well-formed joints. In the U. S. the time of planting extends from October to March. As a rule, autumnal planting is to be preferred. The soil is prepared by plowing and reducing with harrows and cultivators to a good tilth. Furrows are then opened by a double mould-board plow, at distances varying from 5 to 8 feet. The canes, cut into sections of about 2 feet in length, are laid in the bottom of the furrow and the soil thrown over them either by a hand-hoe or by a plow. Some planters prefer not to cut the canes unless they are crooked. When the seed is good, two canes alongside are enough to make a good stand. A third cutting is, however, often laid at the points of union of the canes, making, in the language of the planter, "two canes and a lap" in a row. The total quantity of seed required varies from 4 to 6 tons an acre. After planting it is best to either roll the top of the soil or to smooth the space over the furrows with a hand-hoe, removing all clods which might interfere with the exit of the young canes from the soil. The young canes grow from eyes held on the joints of the parent cane. When spring planting is practiced, the eyes of the cane are preserved from the injurious effects of frost by being preserved between the rows, the top of one cane being spread over the stalk of the one previously cut. This process is called *windrowing*. A light covering of earth, which can be thrown over the canes by running a plow on either side, is sufficient to protect the seed from all ordinary frosts and to prevent it from becoming too dry. If a better protection be desired the seed is preserved in mats, piles of cane carefully laid down and covered with cane-tops and earth. The preservation in windrows is usually preferred to that in mats, unless very cold weather be expected. Cane preserved for seed is subject to disasters due to drying up, frost, insects, and fungous diseases. For this reason the seed preserved for spring planting is often of poor quality, requiring a larger weight per acre.

Young canes are not seriously hurt by frost unless it comes very late in the spring. In the cane-growing districts of the U. S. frosts are not often experienced after Mar. 1. In fields which have long been under cultivation sugar-cane requires generous fertilizing. Superphosphates, potash salts, and cottonseed-meal are the fertilizing materials usually employed. The highest tonnage per acre has been obtained by using 350 lb. of cottonseed-meal, 430 lb. of acid phosphate, and 100 lb. of sulphate of potash.

The sugar lands of Louisiana consist almost wholly of alluvial deposits embracing two types, a light and a dark soil. The cultivation of the growing cane consists in keeping the ground well plowed and free from weeds. As the cultivation goes on it is the general custom to throw the soil toward the row, so that at the time of "laying by" the field is left in ridges, the canes growing on the summits. The cultivation usually lasts until the latter part of June. After the first crop of canes is harvested the stubbles will produce in the succeeding years a second crop and often a third or fourth. In the U. S. the replanting of the fields, however, usually takes place every second or third year, while in tropical countries the fields may run from ten to fifteen, and even a greater number of years, without replanting. The first crop from the fields is known as plant-cane, and subsequent crops as first and second year stubble, etc. The beginning of the cultivation of stubble-cane consists in barring off, that is, in throwing the soil from the stubble by means of a single mould-board plow. In addition to this the stubble is often shaved, that is, cut off smoothly just beneath the surface. At this time it is also customary

to apply the fertilizers. After a few days the soil is thrown to the stubble and the middles broken out and reduced to good tilth, and the subsequent cultivation is the same as that for plant-cane already mentioned. The stubble crops from year to year become harder and contain more woody matter, but the juices are, as a rule, richer in sugar, so that the total amount of sugar per ton is about the same in both plant and stubble crops. In harvesting the canes are cut as near the surface of the soil or as little thereunder as may be with a broad steel knife furnished with a hook on the back, by means of which the laborer by a skillful stroke on either side of the cane relieves it of its leaves, after which the top is cut at the first immature joint and the canes thrown in a pile for subsequent removal to the factory by cart or portable railway. A good laborer will cut from 3 to 5 tons of cane per day.

Culture of the Sugar-beet.—Sugar-beets are grown to the best advantage for sugar-making purposes in northern temperate regions. In going southward, as a general rule, the beet becomes less sweet and more pithy and tends to grow to a larger size. A mean temperature of 70° F. is well suited to the growth of beets of high sugar content. The soil in which beets are planted should be plowed to the depth of about 10 inches and loosened by a subsoil plow to an additional depth of 6 inches. The plowing is often accomplished in the late autumn. In all cases before planting the surface should be reduced to perfect tilth. Any soil suited to the growth of good crops will produce beets, but they do not grow well in a stiff clay. The seeds are planted in rows about 18 inches apart, and covered to the depth of about 1 inch. Deep planting should be avoided, inasmuch as the tender shoots of the young plants are not able to emerge from a very deep covering of earth. From 12 to 20 lb. of seed are planted per acre. When the plants are grown until they show four well-developed leaves, the thinning process is commenced, leaving one vigorous shoot at about every 9 inches in the row. The number of plants per acre is determined in a large measure by the fertility of the soil and the degree of fertilization practiced; but in all cases they should be numerous enough to limit the average weight at harvest-time to a little more than 1 lb. The culture of the beet consists in keeping the soil well stirred and free of weeds. Deep culture is not admissible on account of the danger of disturbing the young plants in their position and of covering up the tops. At the time of laying by, which is about the middle of July, the surface of the soil should be left as smooth and level as possible. The planting in the chief beet-sugar countries extends from the last day of April till the end of May. In California, where are found exceptional climatic conditions, the planting begins as early as January and extends to June. As a rule, the earlier plantings produce the better crops. In Germany and France the harvest begins about Sept. 15, and is concluded by the middle or end of November. In California the harvest begins as early as August and continues until the end of the manufacturing season. The beets can be left without much danger until January, or until there is danger of second growth from the winter rains. In harvesting, the beets are loosened by a digger which passes under them, and are then removed from the soil by their tops and thrown into heaps. The tops with a portion of the neck of the beet are then removed by means of a large sharp knife, and the beets are then ready for preserving in silos or delivering to the factory. In siloing the beets they should be covered as lightly as possible, to preserve them from danger of freezing. If the temperature of the silo becomes too high the beets are apt to be injured.

The manufacturing season begins in California in August, and in other countries in September. The average duration of the manufacturing season is about three months, but in exceptional cases it lasts for four or five months. With the approach of spring, however, the beets rapidly deteriorate, and for this reason manufacturers try to close the season by the end of January.

The production of a beet rich in sugar has become a separate branch of the sugar industry. From an original content of from 4 to 6 per cent. of sugar, the development of the beet has continued until it now shows from 13 to 15 per cent., and in exceptional cases from 15 to 19 per cent.

At the time of harvest certain beets of typical shape and size and of apparently perfect nature are selected and preserved in silos over the winter without having their necks removed. In the following spring the silos are opened and each beet examined separately by taking out a core cut

diagonally through it by an appropriate machine. The juice is expressed from this core and the content of sugar determined thereon. The beets thus examined are classified according to their sugar content. The following table shows the number of beets of each variety placed in each class, as determined by analyses made at the experiment station of the Department of Agriculture in Schuyler, N. Y., in 1893:

VARIETY	No. 1, grade 1 sugar 15 per cent. and upward	No. 2, grade 2 sugar 12 to 14 per cent.	No. 3, grade 3 sugar 10 to 12 per cent.
Original Kleinwanzlebener	25	425	448
Dippel's Kleinwanzlebener	5	263	1,176
Vidua's improved	9	600	784
Deutsche	—	—	476
Jaeger's	—	—	105
Elite Kleinwanzlebener	7	210	224
Totals	57	1,508	3,056

The beets are not materially injured by this boring, and after the examination is made they are carefully protected until all danger of frost is passed, when they are transplanted into a field devoted to this purpose and placed in rows at distances of about 8 feet. Each class is planted by itself, and thus three grades of seed are produced. The first grade is kept especially for the production of special beets of high content of sugar, while the second and third grades are used for the production of beets, which in their turn are planted in large quantities in furnish seed for commercial purposes. It is by the persistent application of this principle of self-selective selection that the sugar-beet has been raised to its present high content of sugar, enabling it to compete successfully with sugar-cane, and even to exclude sugar made from the sugar-cane from the markets of Europe.

Manufacture of Cane-sugar.—The process of making sugar from sugar-cane is very simple. In its most primitive form it consists of crushing the canes between appropriate rollers, and evaporating the juice thus obtained to the crystallizing-point in open vessels. Commercially the process is as follows: The canes, harvested as previously described, are sent from the field to the factory, where they are crushed between powerful iron rollers. In many factories before entering the rolls the canes are passed through a shredder, which tears them into small pieces and thus puts them in a condition to be more evenly fed to the mill and to yield with a given pressure a higher percentage of juice. In the best factories the mills are erected in series of two or three. The first mill usually has three large rolls and the emerging canes, now called bagasse, are conducted by a carrier to a second mill, consisting usually of two rolls, but larger and heavier than those of the first mill. While in transit between the mills the bagasse is generally moistened with steam or hot water, whereby a better extraction of the saccharine matter is obtained, although the resulting juice is more dilute. Occasionally a third mill, similar in construction and operation to the second, is found. To avoid danger of breaking, the rolls are made adjustable to feeds of different magnitudes by means of rubber pads or springs or hydraulic regulators. With careful control, and with canes not too woody, from 75 to 85 per cent. of the saccharine matter contained in the canes may be obtained by milling. Taking into consideration all kinds of milling practiced in sugar-cane countries the world over, it may be said that only about two-thirds of the sugar produced in the canes is obtained by the crushing process.

The bagasse from good milling is conducted at once to a specially constructed furnace, and by its combustion renders the use of any other fuel in the factory unnecessary.

To a limited extent the diffusion process is used in the extraction of sugar-cane. This is described in the section on the manufacture of sugar from sugar-beets. The cutters used for canes to prepare them for the diffusion process are, however, different from those employed for beets. The canes are either run into thin slices by being fed obliquely through hoppers against a revolving horizontal disk carrying radial knives, or else are torn into fine pieces by means of revolving, staggered, circular saws. From 90 to 95 per cent. of the saccharine matters in the cane are obtained by the diffusion process, but the juices are more dilute and the bagasse is left in a condition unsuited for fuel.

The juices obtained from the sugar-cane are treated with excess of lime to neutralize the free organic acids therein contained, heated to the boiling-point, and the blanket of

scum thus produced removed. After standing for some time the sedimentary matters separate and the clarified juice is drawn off and sent to the evaporators. The scum and sediment are passed through a filter-press and the clear juice obtained thereby added to that secured as described above. The evaporation of the juice and its subsequent concentration into crystallized sugar are accomplished as in the sugar manufacture.

Treatment of Sugar-beets.—After the removal of the tops, together with a portion of the neck or collar, the beets are ready for the factory. The upper portion of the beet contains an excess of mineral matter, the introduction of which into the factory would prove injurious to the yield of sugar by preventing its crystallization. The beets are thrown into a trough and moved by a series of screw-paddles against a strong current of water. Adhering soil and sand, the presence of which would render the slicing of the beets difficult by reason of the dulling of the knives are removed by this treatment. After washing, the beets are carried by an inclined water to the slicing apparatus situated above the center of the diffusion battery. In countries where a tax is laid upon the beets they are, after washing, carried onto a weighing-machine, where their weight is noted by an agent of the inland revenue bureau. The beet slicer consists of a revolving, horizontal disk carrying radial knives against which the beets are fed through a hopper. These knives are arranged in such a way as to produce an irregular cutting, usually of a V-shape. The best cuttings are known in France as *manilles* and in Germany as *Schnittzel*. Their irregular form prevents the too close contact of their surfaces in the diffusion battery, and thus permits a free circulation of the diffusion liquids throughout all parts of the system. The theory of the diffusion process rests upon the well-known principle of osmosis. If a crystallizable body in solution be separated from pure water by means of a porous membrane there will be an interchange of such a nature that at the end of a certain time the crystallizable body will be found equally diffused within and without the membrane. The vegetable membranes which compose the cells of sugar beets and sugar-cane easily permit this diffusion to go on. If, therefore, into a mass of finely sliced cane or beets warm water be introduced, it will soon become impregnated with sugar, and after a certain time, depending upon the temperature and the fineness of the cuttings, will contain the same percentage of sugar as the unbroken cells themselves. In practice the water thus impregnated with sugar is passed into another cell containing fresh cuttings, while fresh water is passed into the first cell, and this process is continued until all the cells of the battery, with two exceptions, are in operation. A diffusion battery usually consists of twelve cells. When in operation two will thus be found under pressure, while one will be filling with the fresh cuttings and one will be emptying of the exhausted cuttings. The process once established goes on continuously.

Treatment of Beet Juices.—The saccharine juices extracted from beets require a more elaborate treatment than those expressed from sugar-cane. This arises from the fact that they contain foreign bodies more refractory to purifying treatment and more difficult to eliminate. The preliminary treatment of the beet juices preparatory to condensation is carried on as follows: The juices as they come from the diffusion battery are treated with lime in considerable excess of the quantity required to neutralize their natural acidity. From 2 to 3 lb. of lime are used for each 100 lb. of juice. Beet juices a few moments after expression or extraction become quite dark, and when in a large mass, as in the juice from a diffusion battery, the color is quite inky. The excess of lime precipitates this coloring-matter, as well as a part of the nitrogenous and other impurities present. To remove the excess of lime after the purification, carbonic acid is blown into the mixture, and the temperature is slowly raised until the boiling-point is reached, a little before the saturation is complete. The carbonic acid is obtained from a lime-kiln, which also furnishes the lime for the preliminary treatment. At the end of the saturation with carbonic acid the lime is found in the form of a carbonate of a fine granular texture, which is a great help in the following filtration, preventing the clogging of the filter-cloth. This treatment is technically called carbonatation or saturation. At the end of the operation the whole mass is passed through a filter-press, and the precipitated carbonate of lime and the other solid impurities are separated as press cakes. The emergent juice is of a bright amber color, transparent and apparently quite pure. In practice,

however, it is found to be profitable to repeat the process just described. In the second saturation the quantity of lime used is much less than in the first, not exceeding from $\frac{1}{2}$ to 1 lb. to 100 lb. of juice. The second saturation is followed by a second filtration, and the bright juices thus obtained are ready for evaporation, although they still contain large quantities of soluble materials other than sugar, chief among which are salts of potassium.

The evaporation, concentration, and crystallization of the purified juices, both from beets and sugar-cane, are carried on in the same manner, and one description of the process is sufficient.

Evaporation and Crystallization.—The two chief points to be kept in view in securing the sugar from the saccharine juices, clarified as above described, are the removal of the water and the prevention of the inversion of the sugar during boiling. Evaporation in open kettles is largely practiced in making sugar in a small way. The heat is applied directly to kettles or pans by means of a fire of wood or bagasse, or indirectly by means of copper coils connected with a steam-boiler. As the concentration proceeds the condensed juices are carried to the finishing kettle or pan, fresh juices being added to the others. When the evaporation has proceeded to the crystallizing-point, which is determined by the temperature or the appearance of the boiling material, portions of the mass may also be removed, cooled, and tested. The sugar, still in a liquid state, is put into vessels, where it crystallizes. When the crystallization is complete, the molasses is removed by transferring the mass to hogsheads with perforated bottoms. Sugar-canes are often pushed into the crystalline mass to open up channels for the liquid portions. The sugar thus formed is of a more or less pronounced yellow color and quite moist. When made from cane it retains the natural aromatic flavoring matters of the original juices, and is highly prized, especially by bakers. The process, however, is not an economical one, both on account of the large amount of fuel required and by reason of the loss of sugar by inversion at the high temperature reached in the end process. Even in Louisiana, where this method was once the leading one, it has almost entirely given way to more modern processes.

All modern sugar-factories of a magnitude to be of any commercial importance conduct the evaporation of sugar juices in a partial vacuum. This not only secures great economy in the use of fuel, but also, by reason of the lower temperature which is maintained, avoids all loss by inversion. To avoid confusion, some of the technical terms in use in sugar-factories should be defined. The word juice or liquor is applied to all saccharine liquids of moderate density in the raw state after extraction from the cane or beets, or in the clarified state with its attendant concentration. The term sirup designates the saccharine liquid after its first evaporation but before it is finally boiled for sugar. The expression massecuite is used to designate the mass as it is finally boiled for sugar, and embraces not only the crystallized but also the liquid contents of the vacuum-pan at the end of the boiling. Molasses is a term applied to the separated portion of the massecuite, whether obtained by drainage or by centrifugal action. Multiple effect is the name given to the series of evaporators joined *en suite*, by means of which the juice is reduced to a sirup. When only two are *en suite* it is called double, and when three a triple or multiple effect. They are arranged in such a way as to require steam to be applied only to the first one. The vapors arising from the first pan become the source of heat for the second, those from the second of the third, and so on. This is accomplished by so arranging them as to have the lowest vacuum in the first of the series and the highest in the last. If three pans be used, the reading of the vacuum-scale on the first one will be, for example, 5 inches, on the middle one 15 inches, and on the last one 25 inches, 30 inches representing practically a perfect vacuum.

In point of fact, by this arrangement there is no economy of speed, four pans not evaporating any more than one would at the highest vacuum and with the same amount of steam. The amount of fuel required, however, for a given volume of evaporation is approximately only one-third that which would be required if only one pan were used plus the amount necessary to operate the vacuum-pump. Inasmuch, however, as the quantity of steam required for the pump is the same whether one or three pans be used, there is saved, approximately, two-thirds of the fuel. In practice it is found that no economy is secured by increasing the number of pans beyond three or four. The saccharine liquor is

gradually transferred during the operation to the third pan, from which the finished sirup is removed from time to time or continuously by means of a pump which will create a higher vacuum than that existing in the pan. The process in a multiple-effect apparatus, when once started, is a continuous one, fresh juice entering the first pan and the finished sirup flowing from the last one.

The strike-pan is a boiling apparatus used with a high vacuum in which the sirup is concentrated to massecuite. Its size corresponds to the capacity of the factory, and for those houses which use from 200 to 400 tons of raw material a day the strike-pan will vary from 6 to 10 feet in diameter and from 10 to 20 feet in height, and with a capacity of from 20,000 to 70,000 lb. of massecuite at each strike. Heat is applied in the strike-pan by means of a series of copper coils, one above the other, beginning near the bottom and extending half way or more to the top. These coils of copper are of large diameter, in order to permit the free circulation of exhaust steam, at low pressure, from the engines and pumps of the factory. Live steam is not used in the pan except when the exhaust steam proves to be insufficient. For the manufacture of raw sugar the vacuum is maintained as high as possible. With a good pump and other apparatus, at sea-level, it can be kept at from 28 to 29 inches. In this vacuum the boiling will take place at a temperature of from 120° to 150° F., according to the density of the mass.

The operation is begun by taking into the pan a quantity of sirup large enough, when concentrated to the crystallizing-point, to cover the first coil. By means of the proof-stick the sugar-boiler determines when the sirup has a proper degree of consistence. At this point a considerable additional quantity of sirup is quickly drawn into the pan, whereby a crystallization is produced in the thickened sirup in the pan. The crystals formed at first are too small to be seen with the naked eye, but when some of the mass is put on a piece of glass it is seen to have a turbid appearance. The art of the sugar-boiler consists in feeding these crystals with fresh quantities of sirup, added in such a way as to avoid, on the one hand, the melting of the crystals already formed, and, on the other, the formation of a new crop of crystals known as false grain. When the operation is properly conducted, the pan is gradually filled with the growing mass of crystals, and coil after coil of the heating apparatus is brought into use until all are in operation. After this the boiling goes on with great activity until the pan is full. At the end the further supply of sirup is cut off, usually after the addition of a considerable quantity of sirup, for the purpose of washing the crystals, and the mass is thickened by further boiling until the minimum quantity of water consistent with the proper handling of the massecuite is secured, viz., from 6 to 10 per cent. The large valve at the bottom of the pan is then opened, after the vacuum has been broken, and the massecuite falls directly into a mixer or into wagons in which it is carried to a mixer. When the sirup is rich and pure the massecuite, as it drops from the pan, is already in appearance a solid body. In the mixer the massecuite is kept in motion by revolving paddles, and thus prevented from setting into solid masses, which would be difficult to break up and dry. From the mixer the massecuite passes directly into the centrifugal machines, where the sugar is separated from the molasses. So quickly is this accomplished that within a few minutes after leaving the strike-pan the dry sugar, still warm, may be found in packages ready for shipment to the consumer or the refiner.

The molasses secured by the above process is still rich in crystallizable sugar, and is reboiled for a second crop of crystals. When very rich it can be boiled to grain, as in the first instance, but if too poor for this it is boiled to string proof to the proper consistence, placed in cars in a warm room, and allowed to remain for a week or ten days. By this time the crystallization is completed, and the contents of the cars are thrown into the mixer, well broken up, and the sugar separated in the centrifugal in the manner already described.

The molasses obtained from this second crystallization is sometimes rich enough to be again reboiled, after which it is placed in wagons or large cisterns, and allowed to remain for several months, yielding a third crop of crystals, which when dried form a low-grade sugar. The residual molasses is finally either sold for culinary use or for mixing with glucose to make table sirups, or is sent to the distiller.

Beet-sugar molasses is unfit for table or culinary use on account of the large quantity of mineral salts which it contains. It is either sent to the distiller or the sugar it contains is recovered by combining it with strontium or lime, whereby an insoluble sucrose of the base used is obtained, which is separated from the soluble salts and other impurities by means of a filter-press. In this case it is the residue in the press cake which forms the valuable product. The sucrose therein contained are beaten to a cream with water, and the lime or strontium precipitated by means of carbonic acid. The carbonate of the base is separated by filtration, and the comparatively pure sugar juices obtained are concentrated and crystallized in the usual way.

The Refining of Sugar.—The sugar which is obtained by the above described processes is not white nor pure, and is prepared for table use by the refiner. In the historical sketch above given it was stated that the early processes of refining consisted at first in simply melting and reboiling the crude sugar. Each successive crystallization obtained in this way showed an improvement in color and purity, but the quantity of fairly white sugar finally obtained was a very small part of the raw material originally taken. The aid of clay, lime, and the white of eggs or blood was found to assist in the refining process, but without adding much to the total yield.

In India the term refined sugar includes sugars which have been purified by charcoal strainers and freed from all admixture of uncrystallized sirup, and also the raw native sugars prepared in the following way: The immediate product of the first boiling of the cane juice is known as gurrh or rab, according as the sugar is boiled down to a hard mass, or allowed to remain in a semi-liquid condition. Both gurrh and rab contain some uncrystallized sirup. Gurrh, as a rule, is intended directly for home consumption, and is comparatively seldom used in the manufacture of refined sugar. Rab, on the other hand, is always intended for refining. In the process of refining the molasses known as shira is partially expressed from the rab by the primitive contrivance of a man standing on a pile of bags filled with rab, and working them backward and forward by the movement of his body. The rab partially refined in this way is called putri, and though it still contains a large percentage of shira it is far more compact, and shows more granulation than before pressing. The putri is thrown into a crate covered with a species of water-weed known as siwar (*Vallisneria spiralis*), and the remaining sirup slowly drains out at the bottom of the crate, and the putri gradually whitens into a mealy looking sugar called pachani, and it is then dried in the sun and broken up by being trampled on for some hours. When dried it is known as shakar.

These crude methods in sugar-refining have led to the modern processes, which are so perfect as to permit of the recovery in a state of purity of almost all the sugar in the crudest articles of commerce.

The process of refining is often carried on in connection with the manufacture of sugar from the raw materials. Various methods are employed. In one process the juices are subjected to the action of sulphur-fumes, whereby they become bleached. In the subsequent boiling the mass is left in a less dense state, so that the crystals are more readily separated from the molasses, and more easily washed. When the crystals are dried in the centrifugals they are washed with a little water, and also with a solution of chloride of tin, which give them a bright appearance. Sugar made in this way, especially from cane-juice, is quite pure, and has a white or delicate yellow tint, and is much prized by some consumers. The yield, however, as can be readily seen, is much less than that obtained by the dense boiling before described.

Instead of sulphur-fumes bone-black is also employed in making a white sugar directly in the factory. The bone-black is generally used on the sirups until they are practically decolorized. Sugar made with the use of bone-black is washed in the centrifugals with a little water, followed by a solution of ultramarine. The bluing thus practiced gives a whiter tint to the crystals.

These refining processes are profitable only where there is a good domestic demand for high-grade sugar, and in localities remote from refineries, where the freights attending the shipment of refined sugar materially increase the price.

From an economical point of view the refining of sugar is entirely distinct from its manufacture from the raw materials. It is carried on in the most economical way in large

establishments kept in operation during the greater part of the year. In the U. S. there are in active operation less than a dozen refineries supplying nearly 2,000,000 tons a year.

Following is a brief description of the process of refining sugar on a large scale:

The raw sugar is dumped into vats, where it is stirred with warm water until melted. In this manner a sirup is obtained containing from 80 to 40 per cent. of sugar. The bags and other packages in which the sugar is shipped are washed, and the wash-water added to the saccharine mixture. The liquor thus formed is filtered through bags or filter-presses, to remove suspended matters. Sometimes the liquor is made thinner, and treated with lime and clarified in the manner described for cane juices. After filtration the limpid liquors are bleached with sulphur-fumes, or by passing over bone-black, which is the more usual way. Bone-black is prepared by subjecting bones to distillation in a retort practically excluded from the air. A large part of the organic matter in the bones is by this process converted into carbon, and left in a finely divided state distributed throughout the molecules of lime phosphate of which the mineral matter of bones is chiefly composed. This combination of animal char and lime phosphate has the property of rapidly oxidizing the coloring-matter of sugar solutions, and thus of bleaching them. The freshly burned char is contained in cylindrical vessels of steel or iron arranged in convenient series. The most highly colored solutions are passed first through those filters which have been in use some time, and thus have lost to a certain extent their decolorizing power. The process is continued in such a way that the less colored solutions are finally brought into contact with some fresh char, whereby they are rendered almost if not quite water-white. The more complete the decoloration the larger the percentage of white sugar which will be obtained. The bone-black, when it has once lost its decolorizing power by use, can have it restored by washing in a dilute acid, followed by water, and then burning in specially constructed retorts. These retorts are continuous in their operation, the spent black being fed in at the top and the revived char being removed at the bottom. After repeated using, however, the char loses its virtue, and is then sold for fertilizing purposes.

The nearly white liquor finally obtained is ready without further preparation for treatment in the strike-pan. The general method of boiling is the same as that already described. The crystals are made large or small to meet the demands of the trade and at the will of the sugar-boiler. If a hard crystal be desired the boiling takes place at a lower vacuum, say 24 to 26 inches, while if a soft crystal be demanded the vacuum is made as high as possible, from 28 to 29 inches. After leaving the strike-pan the crystals are dried in the centrifugals in the manner already noted. The still slightly moist crystals, as they come from the centrifugal, may be moulded into cubes and dried (loaf-sugar), or dried in larger masses and cut or broken into approximately cubical pieces (cut or broken loaf), or dried and ground to a fine powder (powdered sugar). The hard crystals are also dried in revolving drums heated by steam, and form thus the granulated sugar of commerce, a form in which by far the larger part of refined sugar now reaches the consumer.

The molasses from the first granulation is reboiled and lower grades of nearly white sugar made therefrom. These sugars are sold under many names, such as coffee A, coffee C, brown sugar, etc. A third and even fourth crop of crystals is sometimes obtained, and finally nearly all the sugar originally present in the crude material is secured in a refined state. The art of the sugar-boiler is constantly brought into use to make grades of sugar which the trade demands, and also to use the material placed in his hands to the very best advantage. When his work has been properly conducted there is finally little waste material left to be sold to the mixers or distillers as "black strap."

In some countries, especially in Great Britain, sugar in the form of large yellow crystals is much in demand. These crystals were first made in Demerara, and hence the name which they bear. They are made by building a very large crystal in the strike-pan and then producing thereon a superficial coating of caramel to give a yellow color. This was formerly accomplished by introducing a quantity of sulphuric acid into the pan just before the strike was dropped. At present tin chloride is chiefly used for coloring the crystals. In making these large crystals, after the sirup in the pan has been reduced to a certain consistence, a large quantity of ordinary granulated sugar is put in the pan, and on

these crystals the larger ones are built in the manner already described.

Relative Sweetness of Beet and Cane Sugars.—In chemical and physical character pure refined sugar made from beets is the same as that made from cane. In the raw sugars, however, and in the sugars made from molasses, there are marked differences. The beet contains a large quantity of alkaline salts, and these bodies are found to some extent in the raw beet-sugars and in beet-molasses. An unrefined beet-sugar has a higher percentage of ash than the same grade of cane-sugar. The aromatic organic ethers and essential oils that give an agreeable odor and flavor to cane-sugar are mostly absent from beet-sugar. A stranger entering a cane-sugar factory during the working season will at once notice the agreeable aromatic odor everywhere present. On the contrary, in a beet-sugar factory, especially if much molasses be in process of manufacture, the opposite will be noticed. Raw or unrefined cane-sugar may be used on the table or in the kitchen, and the old-fashioned open-kettle molasses is a luxury. Unrefined beet-sugar can not be used with comfort on the table, and beet-molasses as a culinary article is unknown. Beet-molasses contains a certain quantity of the sugar known as raffinose, which modifies both the physical and chemical characters of the sugars made therefrom. Even in the refined sugars a difference may be noticed between cane and beet sugars if the samples are kept well stoppered for some time. An air-tight package of granulated cane-sugar will have an agreeable aromatic odor when opened, while beet-sugar in the same condition gives an unpleasant sensation to the nostrils. In respect of the sweetening properties of pure cane and beet sugars there is no difference whatever between the two varieties.

Chemistry.—Until within recent years there has been much confusion in the classification of sugars and sugar-like bodies as made by different chemists. By many authors only those bodies were classed as carbohydrates which contain six atoms of carbon or some multiple thereof, together with oxygen and hydrogen in the proportion to form water. In 1882 von Lippmann published a work in which he took the view first proposed by Fittig, that the carbohydrates were all derived from a hypothetical, heptatomic alcohol having the composition $C_7H_{17}(OH_7)$. From this form by dehydration are produced the anhydrides, such as $C_6H_{11}O_5$ or $C_{12}H_{22}O_{11}$, representing glucose and saccharose respectively.

In 1888 a marked advance in the knowledge of carbohydrates was secured by the publication of Tollens's *Handbook*. Tollens defines carbohydrates as always or nearly always neutral bodies which form only loose compounds, especially with the bases, and consequently all bodies, such as methyl-hydroxyglutaric acid ($C_5H_{10}O_6$) and its lactone acid ($C_5H_8O_6$), as well as the saccharines which possess the general formula of carbohydrates but pass over easily into the form of acids, must be excluded from the list.

According to Tollens the carbohydrates have many common properties, and they possess these properties either in themselves, as, for instance, the glucoses, fruit sugars, and dextrose, or they are easily converted into bodies which do possess them, as, for instance, cane-sugar, cellulose, and starch. In some of the undoubted carbohydrates one of the general properties may be wanting, but there are other properties which are indispensable, and those bodies which do not possess them must be left out of the class even should they be indifferent chemically and have the general carbohydrate formula. According to this view the properties peculiar to the true carbohydrates are the following:

- (a) The power of reducing alkaline metallic salt solutions and of forming a yellow color with alkalis.
- (b) When in solution they must possess the ability to rotate the plane of polarized light.
- (c) They must have the power of fermenting when treated with yeast, with the production of alcohol and carbon dioxide.
- (d) When heated with hydrochloric or sulphuric acid they should produce levulinic and formic acids and humus substances.
- (e) They should have the property of giving a yellow crystalline precipitate when treated with phenylhydrazin acetate.
- (f) They should give characteristic color reactions when treated with acids and aromatic alcohols.
- (g) They should be soluble in water either directly or after hydrolysis with an acid.
- (h) When subjected to strong heat all carbohydrates are decomposed, turning brown at first and afterward black, with a production of many different substances.

Tollens, in accordance with his views, classifies the carbohydrates and nearly related bodies according to the number of carbon atoms which they contain, as monosaccharids having 6 atoms of carbon, disaccharids with 12 atoms, and polysaccharids with 18, 24, or 36 atoms, etc. By this classification the number of true carbohydrates is diminished until it is comparatively small, while the number of carbohydrate bodies is large. The common sugars and carbohydrates, according to the above classification, are grouped as follows:

I. Monosaccharids or glucoses, type $C_6H_{12}O_6$.

1. Dextrose.
2. Levulose, invert sugar, mannitolose.
3. Galactose.
4. Sorbin or sorbose.
5. Different little-known glucoses.

II. Disaccharids or saccharoses, type $C_{12}H_{22}O_{11}$.

1. Cane-sugar.
2. Milk-sugar.
3. Maltose.
4. Trehalose.
5. Melezitose.

III. Polysaccharids.

(a) Crystallizable polysaccharids.

1. Raffinose, $C_{18}H_{34}O_{16} + 10H_2O$.
2. Lactosin, $C_{18}H_{34}O_{16}$.

(b) Difficultly or non-crystallizable polysaccharids.

1. Starch.
2. Inulin.
3. Saccharocolloids, gums, and slimes.
4. Cellulose.
5. Pectin and pectose bodies.

IV. Substances which resemble the glucoses, but do not have either the exact composition thereof or for other reasons are not to be classed therewith.

(a) Substances which contain oxygen and hydrogen in the proportion to form water.

1. Arabinose, $C_5H_{10}O_5$.
2. Cerasinose.
3. Formose, $C_6H_{12}O_6$.
4. Phenose, $C_6H_{12}O_6$.
5. Inosit, $C_6H_{12}O_6$.
6. Dambose, $C_6H_{12}O_6$.
7. Scyllit, $C_6H_{12}O_6$.
8. Quercin, $C_6H_{12}O_6$.
9. Bergenin, $C_6H_{12}O_6$.

(b) Substances which contain more hydrogen than would be necessary to form water with the oxygen present.

1. Isodulcitol, $C_6H_{14}O_6$.
2. Quercitol, $C_6H_{14}O_6$.
3. Pinitol, $C_6H_{14}O_6$.
4. Sennitol, $C_6H_{14}O_6$.

(c) Mannit and its isomers.

1. Mannit, $C_6H_{14}O_6$.
2. Dulcitol, $C_6H_{14}O_6$.
3. Perseitol, $C_6H_{14}O_6$.
4. Sorbit, $C_6H_{14}O_6 + \frac{1}{2}(H_2O)$.

(d) Arabitol, $C_6H_{14}O_6$.

Of the carbohydrates conforming to the above definition dextrose, levulose, galactose, and mannitol are types. They respond to the reactions given, and have been found to possess the composition of ketones or aldehydes of the hexavalent alcohol $C_6H_{14}O_6$. On the other hand, there are carbohydrate bodies, such as arabinose, having the formula $C_5H_{10}O_5$, which are sugars having all the properties of a carbohydrate, and evidently should be classed with those bodies. There is another sugar, erythrose, having the formula $C_4H_8O_4$, which is an aldehyde of the tetratomic alcohol erythritol, and another sugar glycerose having the formula $C_3H_6O_3$, which also has valid claims to be classed with the other sugars. From the researches of Fischer on synthetic sugars it appears that the old classification is hardly a proper one, and a new one based on his work is preferable. It appears from these researches that there is a homologous series of aldehyde or ketone alcohols having the general formula $C_nH_{2n}O_n$ which have these common properties: 1, Sweet to the taste; 2, optically active; 3, reducing alkaline metallic solutions; 4, yielding with phenylhydrazin characteristic crystalline compounds. All these bodies therefore possess the essential characteristics of true carbohydrates and are as a consequence eligible to classification as such. According to Fischer, the classification of the substances which consti-

tute this homologous series, so far as they have been made known, is as follows:

1. Trioses, type $C_3H_5O_3$, typical member glyceroe.
2. Tetroses, type $C_4H_7O_4$, typical member erythrore.
3. Pentoses, type $C_5H_{11}O_5$, typical members arabinose, xylose.
4. Hexoses, type $C_6H_{12}O_6$, typical members dextrose, levulose, galactose, mannose.
5. Heptoses, type $C_7H_{13}O_7$, typical member heptose.
6. Octoses, type $C_8H_{15}O_8$, typical member octose.
7. Nonoses, type $C_9H_{17}O_9$, typical member nonose.

According to Fischer, every asymmetric carbon atom in a carbohydrate molecule makes two forms possible. There can therefore be at least eight hexoses, and each of these is optically paired, making sixteen in all. Of the sixteen possible forms, ten have already been discovered. Of the thirty-two possible heptoses only six have been discovered, and of the 128 possible nonoses only two are known. There is every reason to believe that the series will be extended by the discovery of new types, increasing very largely the number of possible sugars. In the sugars classified as above all those which contain three atoms of carbon or multiples of three are susceptible of fermentation, while the intervening members can not be fermented. Thus only the trioses, hexoses, and nonoses are fermentable.

Natural sugars all have the power of rotating a plane of polarized light, and this quality serves as a basis for optical SACCARIMETRY (*q. v.*). Synthetic sugars, on the other hand, are devoid of rotatory power, and this is due to the fact that they are composed of twinned molecules having opposite rotatory powers of equal value. See STEREO-CHEMISTRY.

All sugars, natural or synthetical, containing three atoms of carbon or some multiple thereof in each molecule, are susceptible to fermentation when treated with yeast. The products of fermentation are chiefly alcohol and carbon dioxide, but a large number of secondary products are formed, such as glycerol and organic acids.

Cane-sugar, sucrose, or saccharose forms a molecule represented by the formula $C_{12}H_{22}O_{11}$. Cane-sugar belongs to the disaccharids, according to Tollens's classification, or to the hexoses according to that of Fischer. Under the influence of acids and certain ferments it undergoes hydrolysis, assimilating a molecule of water and forming equal quantities of two hexoses known as dextrose or glucose and levulose or fructose. The reaction which takes place is represented by the formula $C_{12}H_{22}O_{11} + H_2O = C_6H_{12}O_6 + C_6H_{12}O_6$. From the above it is seen that the two sugars formed are chemically identical, but optically and physically they have very different qualities, one being a right-handed sugar and easily crystallizable and the other a left-handed sugar and crystallizable with difficulty.

Cane-sugar forms compact, monoclinic crystals having a specific gravity of 1.58. Sugar is very soluble in water. At a temperature of 32° F. a saturated solution of sugar in water contains in each 100 parts sixty-five parts of sugar, and at 120° F. eighty-three parts. In pure aqueous solutions of sugar the density of the solution is directly proportional to the quantity of sugar present. Upon this fact is based a method of determining the percentage of sugar in a solution from its specific gravity. The instrument most commonly used is the Brix spindle. (See HYDROMETER.) For instance, a sugar solution which marks 5° Brix contains 5 per cent. of sugar and has a specific gravity of 1.0197, and one which marks 50° Brix contains 50 per cent. of sugar and has a specific gravity of 1.2328. Elaborate tables are found in works on sugar analysis, giving the percentages of sugar for varying degrees of density, and the specific gravities for each degree and half degree of the standard hydrometers in common use. It is only when sugar solutions are free of impurities that these tables can be used.

Cane-sugar does not possess the power of reducing an alkaline solution of copper, but the dextrose and levulose produced by the treatment of cane-sugar with an acid or inverting ferment possess this power. The process of converting cane-sugar into dextrose and levulose is known as inversion or hydrolysis. Upon the property of reducing alkaline copper solutions to suboxide is based the process of chemical saccharimetry.

When cane-sugar is subjected to a strong heat it suffers a partial decomposition, becomes brown, and forms caramel or burnt sugar.

Many oxidizing bodies act upon cane-sugar with great vigor. For instance, if a mixture of cane-sugar and potas-

sium chlorate be touched with a drop of sulphuric acid the oxidation will be so rapid as to produce a brilliant deflagration. Hot nitric acid also oxidizes cane-sugar with the production of organic acids. A saturated solution of cane-sugar stirred with strongest sulphuric acid will lose its water of composition, and will give a porous mass of carbon and humus bodies. Cane-sugar unites with the bases, especially those of the alkaline earths, forming distinct chemical compounds known as sucrares. The sucrares of calcium and strontium play an important part in the separation of sugar from beet molasses.

Statistics.—The total production of cane and beet sugar in the world in 1893-94 was over 7,550,000 tons, and in 1864-95 over 8,500,000. The following table includes all the most important countries producing sugar-cane except China. Most of the sugar consumed in Japan (125,000 tons per annum) is imported.

THE WORLD'S PRODUCTION OF SUGAR FROM SUGAR-CANE FOR THREE YEARS, IN TONS OF 2,240 LB.

Italy.....	55,000	4
Spain.....	40,000	6
Sweden and Norway.....	30,000	10

At present (1895) Canada consumes about 140,000 tons of sugar annually, amounting to approximately 56 lb. per capita, and Australia and New Zealand 175,000 tons annually, amounting approximately to 90 lb. per capita. From the above data it is seen that the English-speaking people of the world are the great consumers if not the great producers of sugar.

Prices of Sugar.—It is difficult to compare modern with ancient prices, not only on account of the change in the weights and names of coins, but especially because gold, which is the ultimate standard of value, has itself varied so much in its purchasing power in the last thousand years.

From the best authorities the prices of sugar in England at the dates mentioned below, calculated to the present value of gold, are as follows:

From 1259 to 1350, \$156 per 100 lb.; from 1351 to 1400, \$237 per 100 lb.; from 1401 to 1540, \$150 per 100 lb.; from 1541 to 1582, \$181 per 100 lb.; and from 1583 to 1702, \$106 per 100 lb. From 1700 to 1800 the price varied through wide limits, but still remained pretty high, being in 1800 about \$38 per 100 lb. From that time the price was much less, being \$16 per 100 lb. in 1810 and \$4 per 100 lb. in 1885.

In the U. S. from 1845 to 1895 the average price, duty free, for fair refining sugar, polarizing about 96 per cent., was \$4.38 per 100 lb. The lowest price recorded for fair refining sugar was, Feb. 21, 1895, \$1.94 per 100 lb. net cash, duty free. The selling price of refined granulated sugar, including the duty, was on Feb. 21, 1895, 4 cents a pound.

SUGDEN, EDWARD BURTENSHAW, Lord St. Leonards, LL. D., D. C. L.; jurist; b. in London, England, Feb. 12, 1781, his father being a wig-maker. He was largely self-educated, and was called to the bar at Lincoln's Inn in 1807. He almost immediately rose to the front rank of his profession by the publication of his *Practical Treatise of Powers*, previous to which he had published (Feb., 1805) his *Concise and Practical Treatise on the Law of Vendors and Purchasers*; was made king's counsel in 1822, and a bench of Lincoln's Inn; was elected M. P. for Weymouth and Malcombe Regis as a Tory; and in 1829 appointed Solicitor-General and knighted; elected M. P. again in 1830, and sat in the Short Parliament which passed the first reform bill, of which he was one of the most persistent and shrewd opponents; was sworn member of the privy council 1834, Lord Chancellor of Ireland 1835, and again 1841-46; Lord High Chancellor of Great Britain from Mar. to Dec., 1852, being raised to the peerage. He was a deputy lieutenant for Sussex, a trustee of the British Museum, and lord high steward of the borough of Kingston-on-Thames. Although a Conservative he effected reforms in the law of contempt of courts, and in the laws relating to the conveyance of the property of infants, lunatics, mortgages, etc. He was recognized as the highest authority on the law of real property, and as the first practitioner of his time in the court of chancery. D. at Boyle Farm, near Thames Ditton, Jan. 29, 1875. Besides his treatise on *Powers*, and great work on the law of *Vendors and Purchasers* (which has gone through many editions), he published many technical works of lesser importance, including *A Handy Book on Real Property Law* (1858). See *Irish Law Times* and *Law Times* for Feb., 1875.

F. STURGES ALLEN.

Suggestio Falsi: See FRAUD.

Suggestion: a great class of phenomena typified by the abrupt entrance from without into consciousness of an idea or image which becomes a part of the stream of thought

and tends to produce the muscular and volitional effects which ordinarily follow upon its presence. I suggest a course of action to my friend—he may adopt it. Besides this fact of ideal suggestion there is what may be called physiological suggestion, covering the same class of phenomena in cases where the suggestion does not attain the standing of a conscious image, but remains subconscious. It is called physiological because the nervous process, as in all cases of very faint degrees of consciousness, is largely self-acting or reflex. By physiological suggestion, therefore, is meant the bringing about of a reaction subconsciously by means of an extra-organic stimulus.

The clearest examples of such suggestions occur in sleep. Words spoken to the sleeper are intelligently answered. Positions given to his limbs lead to others ordinarily associated with them; the sleeper defends himself, withdraws from dangers, etc. The early development of the child's consciousness proceeds largely by such suggestions. Before mental images are definitely formed and subject to association, we find many motor reactions stimulated by such physiological suggestions from the environment.

From physiological the child passes to sensori-motor suggestion, the type of reaction which illustrates most clearly the law of dynamogenesis. In this case it is a sensation, a clear state of consciousness, which liberates motor energy and produces movement. Besides the inherited sensori-motor couples, which are numerous and well marked, other reactions grow up early in life and become habitual. Of the latter the following may be mentioned in particular:

Sleep-suggestions.—The early surroundings and methods of inducing sleep become powerful re-enforcements of the child's drowsiness, or even substitutes for it.

Food-suggestions and Clothing-suggestions.—These represent the spheres of most frequent and highly spiced joys and sorrows, and their reactions soon take on the involuntary and yet highly purposive character which marks our adult attitudes toward dress and the table.

Suggestions of Personality.—The child shows preferences for individuals at a remarkably early age. He seems to learn and respond to a personal presence as a whole. Probably the voice is the first indication of his nurse's or mother's personality to which he responds, then touch, then the sight of the face.

Imitative Suggestion.—The simple imitation of movements and sounds, clearly manifested about the seventh month of life. See IMITATION.

In *ideo-motor* or *ideal* suggestion we pass to the motor aspects of images, reproductions; and here the motor accompaniments are largely associations and follow the laws of association. As soon, further, as reproductions come up, with their suggested trains, we find the rise of will; that is, they become stimuli to the voluntary consciousness. Yet there is a state of conflict and hindrance among presentations which is mechanical in its issue, the attention being drawn in a reflex way. So states of vexation, divided counsel, conflicting impulse, and hasty decision against one's desire for deliberate choice. We often find ourselves drawn violently apart, precipitated through a whirl of suggested courses into a course we feel unwilling to own as our own. This is the case in the disease called *aboulia*, or loss of will. The man is prey to conflicting impulses. This state, called by the writer deliberative suggestion, characterizes many actions of the young child before will is clearly exercised.

Organic Stimuli to Movement.—In general, any condition of the organism, be it active or passive, which is sufficient to reach consciousness, tends to muscular expression, either natural or acquired. Any derangement of the digestion, respiration, or circulation quickens or deadens muscular tone, and comes out, if not in the face, yet in the conduct of the man. The muscular feelings themselves, so large a portion of the general sensibility, reflect direct changes in the tendency and direction of motor reactions. Diseases of the nervous system find their diagnosis in their effects upon the muscular apparatus: paralysis means rigidity; epilepsy, convulsions; sleep, flabbiness of the muscles. The effect of organic stimulation upon the motor consciousness is best seen in conditions of pleasure and pain. Among direct or native reactions an important class are called expressive; they are differentiated muscular movements which reflect uniformly various affective states of consciousness.

Pleasure-suggestion and Pain-suggestion.—Perhaps the most direct and invariable stimulus to involuntary movement is pain; and its motor force is independent, as it seems, of the intrinsic experience of which it is the tone.

The motor force of a sensation of light, for example, may be in direct antagonism to the motor force of the pain which the light causes to a diseased eye. Despair begets inaction, but the painfulness of it begets restlessness. This is only to say that the tone is an element of sensibility apart from the sensation it accompanies, and that both the one and the other have motor force.

Yet the fact that there are no experiences absolutely indifferent as respects pleasure or pain gives the motor aspect of them an universality and importance which must be acknowledged and provided for in any mental theory. It is a question answered often in the negative whether any course of conduct is ever pursued without primary reference to the pleasure it will bring or the pain it will avoid. However this question may be answered, it may be said at this point that no line of muscular reaction is possible in which an element of motor discharge due to pleasure or pain has not entered. This must be true if the fundamental position is true that every ingoing process alters the equilibrium of the central system and modifies the direction of its outward tendency. Pleasure and pain arising from bodily states may therefore be called the most general internal stimuli to the reactive consciousness.

Motor Spontaneity.—The observation of infants clearly tends to show that movement is no less original a fact than feeling. It is impossible to say whether all antenatal movements are in response to feeling conditions, as claimed by some, just as it is impossible to prove that the beginning of feeling is possible only after sufficient physical organization to make motor reaction possible, as claimed by others. It is altogether probable that the two kinds of phenomena are equally original, and depend upon each other. This is certainly the case, at any rate, at the dawn of independent life. Internal conditions of the organism itself are sufficient stimuli to an endless variety of movements. Such reactions, which are simply the discharges, the outbursts, of the organism, independent of definite external stimulation, are called spontaneous. So the incessant random movements of infants and the extraordinary rubber-like activity of the year-old child.

The movements of infants seem to indicate greater suggestibility than is found in adults. A child's extreme restlessness is due to a high feeling of potential or readiness of discharge; and fatigue is accompanied by a correspondingly complete collapse of muscular movements. This follows from the mobility of the infant's cerebral elements before they are pressed into definite connections and systems which give them greater inertia, on the one hand, and greater general capacities for continued expenditure on the other. Upon this superfluity of motor energy is built up the so-called play instinct, which is not definite enough in its channels to be classed properly as an instinct.

J. MARK BALDWIN.

Suhm, soom, PETER FREDERIK: historian; b. in Copenhagen, Denmark, Oct. 18, 1728; studied law and philology at the university of his native city; settled in 1751 in Trondhjem in Norway, where he lived till 1765, devoting himself to the study of Danish and Norwegian history and antiquities in preparation for his great works. D. in Copenhagen, Sept. 7, 1798. Among his many writings relating to the history of Denmark may be mentioned *Forødg til Forbedringer i den gamle danske og norske Historie* (1757); *Om de nordiske Folks ældste Oprindelse* (1770); *Kritisk Historie af Danmark i den hedenske Tid* (4 vols., 1774-81); *Danmarks Historie* (14 vols., 1782-1828). In spite of its many faults of style and arrangement this last still remains the greatest work of its kind in the Danish language, the chief authority from which later historians have borrowed. By his *Letter to the King* (1772), indorsing the conspiracy against Struensee and calling upon Christian VII. to restore the ancient liberties of Denmark, he became for the moment the most popular man in the North. Both as patron and author he devoted himself to the advancement of freedom and culture. His magnificent library, containing 100,000 volumes, he bequeathed to the Royal Library. Of *Scriptores Rerum Danicarum Mediæ ævi* he edited vols. iv.-vii. (1776-92). Revised by D. K. DODGE.

Suicide [Lat. *sui*, of one's self + *ca'dere*, slay, kill]: intentional death by one's own hand. Among the ancients

suicide was considered neither a crime nor dishonorable, Demosthenes, Themistocles, Mark Antony, Cleopatra, Hannibal, and many others having chosen this way of ending their days. The Scriptures and the Apocrypha furnish examples, as Samson, Eleazar, and Judas Iscariot. In modern times history furnishes numerous striking suicides. The famous suicides among the ancients followed various motives, the vindication of honor being a common object. Mithridates and Hannibal died in this way rather than be taken prisoners. Others have committed suicide through false pride or timidity: a striking case in point was the death of Cato; determined not to live under the despotism of Cæsar, he stabbed himself, but, having fainted, his wound was dressed. When he recovered he tore off the bandages, let out his entrails, and expired.

Many writers have defended this crime, the most able of whom were Madame de Staël, Gibbon, Hume, Schopenhauer, and von Hartmann. Suicide is rarely committed, however, except when the functions of the brain have been impaired and the action of the mind perverted and directed in improper channels.

Suicide has sometimes been epidemic in character. A remarkable epidemic prevailed in Versailles in 1793; the number of suicides in that year reached 1,300, which was greatly disproportionate to the population. Instances have been cited where children have followed the example of one of their number and have taken their own lives. An epidemic of suicide took place in the army of the First Napoleon, and it was only after a strong appeal made by the emperor to the pride and courage of the men in the ranks that it was finally stopped. One of these outbreaks followed the suicide of a convict, who hanged himself to the crossbar of his cell. Five others hanged themselves on the same bar within two weeks. The public prints probably have much to do with the increase of suicide. A morbid person who reads the account of such a case will very often have a train of thought started that will end in the com-

The consideration of suicide from the medical point of view has cleared up many mooted points, such as the degree of responsibility the person is under, the degree of prevention possible, etc. In certain forms of insanity the impulse to suicide is now a recognized symptom, notably in all the disorders which involve melancholia. Alcoholic mania is liable also to issue in this impulse. The peculiar liability of persons whose mental balance is at all weakened to the influence of suggestions of all kinds makes it a necessary part of competent medical treatment that any accounts of suicide, murder, or suggestions of death be kept from them. On the other hand, solitary confinement is found to increase the number of suicides; probably because by diminishing the number of the patient's interests his thought is brought home more forcibly to his own condition, grievances, etc.

Statistics.—Thorough and adequate statistics of suicide are not to be had. Those now given are current ones, and should be quoted only with reservation. In Roman Catholic countries the number of suicides is considerably less than in Protestant countries (about half), the figures in the aggregate for Protestant countries being about 175 to 200 for each million of the population. As to the difference between men and women, suicides are oftener men by about three to one.

From Table I. (from Morselli) and other sources we get the average annual number of suicides per million of inhabitants: Denmark, 258; Germany, 175; Norway and Sweden, 100; France, 150; to which may be added England and the U. S., each 70. Among uncivilized and barbarous tribes and peoples, suicide is practically unknown. It is therefore peculiarly a disease of civilization. In all countries it is more frequent among the mercantile than among the professional classes; and more frequent among the responsible heads of institutions, business houses, etc., than among the dependent classes represented by clerks. Indeed the fact of responsibility seems to be a prevailing cause of suicide. Those, on the contrary, who live a most precarious life, such as the day-

mission of the act. Favorable opportunities for the accomplishment of self-murder will also produce a sudden irresistible impulse. People who have gone up into towers and monuments, or above precipices, have often refrained with difficulty from casting themselves down.

laborers, who may be thrown out of employment at any moment, seem to take their chances with less brooding and personal violence. There is here a discrepancy between the tendency to murder and that to commit suicide; for the murderers are more common among the laboring class, or

still lower classes. Education also seems to increase the propensity to commit suicide. One of the defects of most statistics of suicide is that they do not take account of the unsuccessful attempts at self-destruction, in which the person is equally a suicide.

LITERATURE.—Murelli, *Suicide* (London and New York, 1898); Legoyt, *Le Suicide Ancien et Moderne* (Paris, 1894); statistics contained in successive *Genius Reports* of the different governments; Lewis, *History, Literature, etc., of Suicide* (London, 1883); full list of titles in *Nides and Quince* (1890), p. 499; Tuke, article *Suicide* in *Encyc. of Psych. Medicine* (London, 1892), where statistics are given down to 1890.

J. MARY BARROWS.

SUICIDE IN LAW.—The legal definition of suicide is intentional self-murder by a person of criminal responsibility, in point of age and mental condition. According to Bracton, the early English law treated suicide as a felony, punishable by the forfeiture of lands in case it was committed to escape conviction for a crime, by the forfeiture of goods in all other cases. (2 *De Legibus*, ch. 31.) Later English law imposed the forfeiture of goods and chattels real in all cases. The rule was avoided frequently by a finding of the coroner's jury that the suicide was insane, and was formally abolished in 1570, (32 and 34 Vict., ch. 29.) From an early day the practice prevailed of burying suicides at crossroads with a stake through the body; but it is said to have been without warrant in the common law. (9 *Shepherd's History of Criminal Law*, p. 105.) Its origin is doubtful, but has been ascribed to a Teutonic custom taken up into the canon law. (Guisey, *Penal Laws against Suicide*.) The object of impaling the body appears to have been to keep the ghost from wandering about in the discomfort of the living. (Stranahan, *Suicide and Insanity*, London, 1896.) Parliament abolished the practice in 1828, and later statutes authorize the interment of suicides in churchyards or burial-grounds, with such funeral services as those in charge of the body may provide. (45 and 46 Vict., ch. 19.) The Roman law dealt very leniently with suicide, even to the extent of legalizing it in various circumstances. During the later empire and the Middle Ages the legal rules upon this subject underwent a radical change, produced not only by different ethical and religious views but by political considerations. It was argued that "there could be no patient endurance in the state unless there was patient endurance in the citizen. If the people resorted to suicide to escape trouble, so would the state, and all social order would be at an end."

In the U. S. suicide is not treated as a crime. It is deemed unlawful, however, and a person who unintentionally kills another while attempting to commit suicide is guilty of criminal homicide. (*Commonwealth vs. Mink*, 129 Mass. 422.) At common law a person who kills another at the latter's request, or who persuades another to kill himself, or who agrees to join another in committing suicide, is guilty of murder. Such is still the rule in England, although it is improbable that one who joined another in a common attempt at suicide, but who escaped, would be punished capitally. An unsuccessful attempt at suicide is a common-law misdemeanor. In some of the U. S. such an attempt is punishable as a statutory felony, as is the offense of aiding another to commit suicide, and that of abetting another to attempt suicide. (See New York Penal Code, §§ 172-174.) The Indian penal code provides a severe punishment for persons aiding minors or incompetents to destroy themselves than for those who aid the suicide of sane adults. (§§ 305 and 306.) Macaulay, in his report of the draft of this code, argues strongly against the common-law rule which places the abettor of suicide in the same category with the abettor of murder. (See Wharton, *On Homicide*, § 815, note.) The punishment of one who attempts suicide and fails has been criticised as putting a premium upon the successful completion of the suicidal act.

The law of Scotland does not treat suicide as a crime. It does provide for the sequestration of the suicide's movables; but the proceeding leading to such sequestration is civil and not criminal, and the next of kin to the deceased must be made parties. The proceeding is practically absolute. (Erskine, *Principles of the Law of Scotland*, p. 530, § 39, Rankine's ed., Edinburgh, 1860.) There is no warrant in law or practice for the infliction of any punishment or indignity upon the body of a suicide in Scotland. 1 Hume, *Commentaries on the Criminal Law of Scotland*, p. 309; *Earl of Eglinton vs. Campbell*; Macleod's *Criminal Cases*, 504-551.

The consequences of suicide in life-insurance cases are

discussed in the article on LIFE-INSURANCE under the heading *Perfection*. See also Richards, *On Insurance*, § 159; *Smith vs. National Benefit Society*, 120 New York 85; and *Thom. Life Insurance Company vs. Adams*, 150 United States 499.

FRANCIS M. HARRIS.

Su'idæ [Mod. Lat., named from *Sus*, the typical genus, from Lat. *sus*, hog;] a family of artiodactyl ungulate mammals, of the section *Quadrupedæ* or *Non-ruminantia*, typified by the common hog. The form in all is essentially like that of the domesticated hog, but mostly less gross; the feet are unguligrade (i. e. with the toes only touching the ground), and the external toes and hoofs are reduced in size and do not assist in progression, the median third and fourth of normal series only being functional; the snout is distended and provided with a cartilaginous ring, and in the disk the nostrils are open and forward; the mammae are in considerable number (four in fem, ventral as well as inguinal); the back has no dorsal scent-gland; the tail is short or rudimentary; the tegumentary appendages are developed as stiff bristles; the orbits are directed outward and forward; the occipital bones have long deflected styiform paroccipital processes in front of the occipital condyles; the zygomatic processes overlap the malar bones; the articular surfaces for the lower jaw are transversely convex, antero-posteriorly convex, and limited by no post-glenoid processes; the pterygoid bones are twisted and reflected outward, the crest continued upward and backward into the temporal region; the malar bones are elongated, and have long inferior processes; the teeth are generally in full number, i. e. M $\frac{1}{2}$, P, M, $\frac{1}{2}$ (4), C, $\frac{1}{2}$, I, $\frac{1}{2}$ (3) $\times 2 = 44$; the molars have corrugated cusps, presenting, when worn, deeply sinuated insular areas; the canines of the upper jaw, in the males, are more or less twisted outward and upward, and parallel with the lower. In their anatomy the feet offer characters shared with the wart-hogs and peccaries, and differentiating from the hippopotamids. The living representatives of the family are peculiarly peculiar in the Old World, although in the Tertiary epoch species appeared to have existed in America. Exclusive of the domesticated forms, fifteen species have been recognized. Twelve of these belong to the genus *Sus*, and are all peculiar to Asia, except *S. acrota* (the wild boar of Europe) and *S. senegalensis* of Northern Africa; the genus *Potamochoerus* is confined to West Africa, the single species of *Bobakia* to Celebes and a few of the adjoining islands, and a single species in India and the Archipelago exemplifies the very strongly marked genus *Bobakia*. The domesticated swine are subject to great variation, and Gray even differentiated them into two peculiar genera—*Scofo* for most of the breeds, and *Centurus* for a peculiar race of Japan and China, distinguished by the strongly defined concentric wrinkles of the face. See BARROWS, BODDIE-VAZZ, and SWINE.

Revised by P. A. LUDAN.

Su'idæ [= Lat. = Gr. *Σούιδæ*]; lexicographer. Of his life nothing is known; even the age in which he lived is uncertain, though it may be fixed not later than the twelfth century. His book contains explanations and notices of Greek words and names, illustrated by extracts from older Greek writers. It has evidently gone through many hands before reaching its present form, and it is generally of very little critical value; but as many of the words from which it quotes passages are lost, it has great historical interest. Editions by Gaisford (Oxford, 1834); Bernhardy (Halle, 1834); and Bekker (Berlin, 1854).

Suine, or Butterine. See BUTTER, ARTIFICIAL.

Sukhāvati [Sanskrit, paradise of pleasures]; the heaven over which, according to the Mahā-yāna, or "Great Development" of Buddhist doctrine, a Dharmā-Buddha (see DHARMA-BHONAS) called Amitābha presides, and where the saints, exempt from suffering, death, and sexual distinction (but not from rebirth), may live for countless ages in absolute bliss. Summer and winter are there unknown; the sun never scorches and cold winds never blow; sweet flowers shed their perfume around, and birds of the most beautiful plumage sing day and night of the five chief virtues, the five sources of moral power, and the seven steps in knowledge, and the listener is so affected by their music that he can think of nothing but of Buddha, His law, and His Order. Among the Chinese this paradise is called *Taishan*, the Pure Land in Japanese, *Sōdō*, because its inhabitants are free from the five impurities of this world. Rebirth in Sukhāvati can be secured only by unswerving faith in Amitābha, by fervent prayer addressed to him, and by the practice of every virtue. Amitābha is not only the Buddha of

"boundless light," but also of great mercy and sympathy. His worship is peculiar to the northern school of Buddhists, among whom it takes the place of *NIRVANA* (*q. v.*), which is too difficult of attainment. Sukhāvati is situated in some universe in the far West, and hence is known as the "Paradise of the West."

Sula Islands (Dutch, *Soela*): a group of three islands and many islets in the Dutch Moluccas, E. of Celebes and N. W. of Buru, between lat. 1° 40' S. and 2° 30' S., and 124° and 127° E. lon. Area, 2,590 sq. miles. The largest and westernmost is Taliabu (70 miles long and 15 broad); immediately E. is Mangola, the second in size, and S. of the latter is Besi, the smallest but most thickly populated, and containing Senana, the capital. Pop. about 7,000, formerly six times as large, but depopulated by pirates and slave-merchants. The islands are prosperous under Dutch management. M. W. H.

Suleiman': Ottoman prince. After the battle of Angora (1402) he, as the eldest surviving son of Bayezid I., ascended the throne at Adrianople, but was overthrown by his brother Musa (1410). The Ottoman historians do not consider him a sultan, inasmuch as he reigned only over a part of the empire. E. A. G.

Suleiman: the name of two Ottoman Sultans. **SULEIMAN I.**, EL KANOUNI, the Legislator, often called the Great, the Magnificent, the Sublime (1520-66); b. in 1495, son of Selim I. His reign is a series of generally successful wars, during which he conducted thirteen campaigns in person. In 1521 he crushed a rebellion in Syria, concluded a treaty with Venice, wherein she promised an annual tribute of 10,000 ducats, and captured Belgrade. In 1522 he subdued Rhodes, expelling the Knights of St. John of Jerusalem, whose stronghold it had been 214 years, who found an asylum at Malta. In 1526 he concluded a partial alliance with Francis I. of France against Charles V.; broke the Hungarian power at the battle of Mohacz, where King Louis and 25,000 Hungarians were slain, and brought to Constantinople 100,000 Christian captives, the royal jewels of Hungary, and the precious library of Matthias Corvinus. Besieging Vienna with 120,000 men and 400 cannon, he was repulsed (1529); concluded an offensive and defensive alliance with Francis I. (1533); and took Bagdad from Persia (1534). Meanwhile his admiral, Khafreddin Pasha, terrorized the Mediterranean and subjected Northern Africa. Moldavia and the Khan of the Crimea made submission (1538). Venice, after a disastrous war, purchased peace by promising annual tribute of 300,000 ducats (1539), and Austria, by like tribute of 50,000 ducats (1547). He conquered Persian Kurdistan, captured Van and Tebriz, and partially subdued Georgia (1548). Austria fared better in the next war, defeating the Ottomans with fearful loss in their five months' siege of Erlau (1552). Though Suleiman formed an offensive and defensive alliance with Henry II. of France, dissensions prevented real benefit to either. Fruitless wars followed with Persia (1554-55) and with the Hungarians (1558). Instigated by his favorite, Roxelana, who sought the succession for her son, he put to death his oldest son, Mustapha (1553). Enraged with his son Bayezid, who fled to Persia, he paid the Shah Tahmasp 400,000 gold pieces to insure the murder of the fugitive and of his four sons (1561). To break the naval power of Spain and control the Mediterranean he attacked Malta, but was defeated with the loss of 20,000 men (1565). Carrying on a last war with Austria, he died at the siege of Szigeth (1566), which, after an heroic resistance, fell three weeks later. Meanwhile the death of Suleiman was kept secret, that his successor, Selim II., might have time to reach Constantinople from Kutahia. During his reign the Ottoman empire reached its acme and began its decline. The discipline of the janissaries was relaxed; the harem, in the person of Roxelana, first began to exert undue and hence pernicious influence, and expenditure was carried to its utmost extravagance. More fatal still, during the latter part of his life, Suleiman partially withdrew into Oriental seclusion, leaving affairs to his ministers. Yet this was the golden age of Ottoman jurisprudence, literature, and art. Suleiman remodeled and almost recreated the code, determined ecclesiastical procedure, introduced a less vicious system of taxation, and erected the mosques of Suleiman—the masterpiece of Ottoman architecture—of Selim, the Shahzadeh, Djeanghir, and the Hasseki. He had statesmen and generals of unusual ability in Ibrahim Pasha, Rustem Pasha, and Sokolli Pasha. His admirals, Khafreddin Pasha, Dragut Pasha, and Piali Pasha, were the most skillful naval commanders Turkey has pos-

sessed. But Suleiman was the spoiled favorite of Ottoman fortune, and his successes were mainly won during the early years of his reign. Though he extended the boundaries of his empire, he left it at his death weakened and exhausted. —**SULEIMAN II.** (1687-91), b. in 1642, the son of Sultan Ibrahim. Timid and incapable, he committed the administration of affairs to his vizier, Kupruli Zadek Mustapha Pasha, the Virtuous, who was slain, with 28,000 Ottomans, at the terrible defeat of Selankemen (Aug. 19, 1691), two months after the death of his master. E. A. GROSVENOR.

Suleiman Pasha: Ottoman prince; son of Orkhan and grandson of Osman I. He captured Tzyppe and Gallipoli (1357), the first territorial acquisition made in Europe by the Ottomans. He was killed by a fall from his horse in 1359, and his father died of grief in 1360. E. A. G.

Sul'idæ [Mod. Lat., named from *Sula*, the typical genus, from Icel. *sula*, gannet]: a family of swimming birds of the order *Steganopodes*, limited to the gannets. The neck is moderately long, although shorter and stouter than in either the pelicans or cormorants; the bill about as long as the head, straight, but with the tip decurved, with the lateral grooves well defined, composite as in the other members of the group, and with the edges serrate; narial openings lacking; no gular pouch developed; wings moderately long and pointed; tail long and cuneate, and with twelve to fourteen feathers; tarsi moderately short; toes (four, as in all *Steganopodes*) well developed and connected by a full membrane. The skull is of the desmognathous type, and exhibits modifications co-ordinate with the external characteristics. The species are almost exclusively marine, and one or more may be found on the seacoast of every country. See GANNET. Revised by F. A. LUCAS.

Sulliman' Mountains: a chain of mountains forming the boundary between India and Afghanistan. They range from N. to S., and reach their greatest height, 11,300 feet, in Takht-i-Suliman, in lat. 31° 25' N. They connect S. with the Kurlekhi Mountains of Kelat, and N. with the Seftid Koh, which is 15,622 feet high and ranges from E. to W. The descent toward India is steep, but gentle toward the Afghan plateaus; the valleys drain eastward to the Indus. The most convenient ascent to Kandahar is effected along the Gomal from Dera Ismael Khan on the Indus.

Revised by M. W. HARRINGTON.

Sull'na: the name of the central delta-branch of the Danube. The Danube, at 45 miles from the coast, divides into the Kilja and Toulcha branches, the former conveying more than half the entire discharge. The latter again divides into the Sulina and St. George branches. The Kilja and St. George mouths are 38 miles apart, and the Sulina mouth nearly half way between. The European Commission of the Danube, representing eight European states, was created by the treaty of Paris (1856), for the purpose of removing obstructions to navigation and deepening the channel, and its powers were prolonged until Apr., 1904, by the treaty of London (1883). This commission has so far succeeded that the Sulina branch is navigable by the largest vessels. (See HARBORS.) The town of Sulina, at the corner of the right bank and the Black Sea, originally a miserable fishing-village, has remarkable public works. Pop. (1889) 4,315. E. A. GROSVENOR.

Sul'lotes [deriv. of *Suli*, in the Cassopeian Mountains, formerly their chief village]: a band of 1,500 Albanian Christian warriors who forced the Ottomans to acknowledge their independence about 1730. In 1788 and again in 1792 they successfully resisted Ali Pasha of Tepeleni, who undertook their subjection. From 1799 to 1803 they were blockaded and practically besieged in their mountain fastnesses by Ali Pasha; their strongholds were gradually captured, despite desperate resistance, and they finally surrendered on favorable terms. The conquerors violated their oath, and men, women, and children were indiscriminately massacred. Only a few escaped. The story of the twenty-two Suliote women, who, rather than fall into the hands of the Ottomans, hurled their children from a precipice and then leaped after them, is everywhere known. Marco Botzaris was a Suliote. They were avaricious and haughty, but loved their freedom above all. E. A. GROSVENOR.

Sulla, or **Sylla**, LUCIUS CORNELIUS, surnamed FELIX: dictator; b. 138 B. C.; was noted in youth for his vices, but distinguished himself under Marius as a cavalry leader in the Jugurthine war, and it was through his skill as a negotiator that Jugurtha was surrendered to the Roman general.

From this moment Marius feared and hated him as a rival. In the war against the Cimbri and Teutones (104-101), Sulla commanded with distinction, and in 92 he was sent as proconsul to Cilicia, where he defeated Mithridates, the general of Mithridates, reinstated Ariobaranes as King of Cappadocia, and received an embassy from Arsaces, King of Parthia. In the Social war both Sulla and Marius commanded with success, but it was Sulla who defeated Popilius Mithras, the chief of the Samnites, and took Beneventum, their capital. For the year 88 he was elected consul almost unanimously, and, to the deep mortification of Marius, appointed commander in the Mithridatic war, a war which Marius had in many ways instigated, in the hope of being chosen general. By means exceedingly violent, though in form legal, Marius succeeded in subverting the appointment of Sulla and getting himself appointed, but during the riot which took place in Rome Sulla escaped to Nola in Campania, where his army was stationed. Followed by the rank and file of his army, he now marched on Rome. Marius fled to Africa, and Sulla was perfect master of the situation; but realizing his dependence upon the army, which was eager for the spoils of an Eastern war, he soon left the city and proceeded with the army to Greece. He stayed away four years (87-83). Shortly after his departure he was declared a public enemy; his property was confiscated; his friends were persecuted or slain. Marius returned, and the Marian or popular party dominated in Rome and Italy. But of all this Sulla took no notice; he simply prosecuted the war. Sulla took Athens by storm in 86 and gave it up to plunder. Shortly after he routed one of the hostile armies at Chæronea; next year he totally destroyed another at Orchomenus, and having expelled Mithridates' troops from Greece and pacified the country, he crossed the Hellespont in 84. Pressed at the same time by another Roman army sent out by the Marian party under Plautius and Probus, ill supported by his Greek subjects in Asia, who found him as unamiable as the Romans, and nearly exhausted by his enormous losses in Greece, Mithridates now sued for peace, and after a personal interview between him and Sulla a treaty was concluded, according to which he returned all his conquests in Asia, surrendered a fleet of seventy large vessels, and paid 2,000 talents. Sulla now turned against Phœnicia, whose soldiers deserted him, and who committed suicide; he then regulated the affairs of the province of Asia, from whose cities he made enormous contributions, and finally set sail for Italy, where he landed at Brundisium in the spring of 83. His soldiers were now rich, and they knew that the final success of their general was a condition of the enjoyment of their riches; they clung firmly to him, and he acted cautiously. Marius was dead, but his son was consul and his party in power, strengthened by an alliance with the discontented Italian nations. The final battle was at the gates of Rome, where Sulla's veterans defeated a large body of the Samnites. Sulla was made dictator for life. It was not his purpose, however, to establish a monarchical constitution in Rome. The legislation which he enacted as dictator, the so-called *Leges Corneliae*, aimed simply at the restoration of the old aristocratic constitution, the extension of the authority of the senate, the restriction of the power of the tribunes, etc. In order to establish this constitution firmly and safely, he first determined to extirpate its adversaries, the Marian party. Thousands of men fell under his proscription; that is, they were outlawed and slain, and their property was confiscated and given to soldiers else. He then attempted to form a steady support for it by settling his veterans in military colonies on such Italian soil as had been confiscated in the Social war or afterward, and by organizing a body-guard stationed at Rome. When he considered his work finished, he assembled the people, abdicated the dictatorship, retired to his villa at Puteoli, and returned to the lazy, voluptuous habits of his youth. His death, which occurred in 78 B. C., was hastened by his debaucheries.

Revised by F. M. Conway.

Sullivan: city; capital of Monticello co., Ill.; on the Chi. and R. Ill. the Pac., Des. and Evansv., and the Wabash railways; 14 miles N. W. of Mattoon, 25 miles S. E. of Decatur (for location, see map of Illinois, ref. 7-Ft.). It is in an agricultural and stock-raising region, and contains 2 State banks with combined capital of \$53,000, and 3 weekly newspapers. Pop. (1890) 1,365; (1900) 1,468.

Sullivan: town (founded in 1843); capital of Sullivan co., Ind.; on the Evansv. and Terre Haute and the Ind. and Ill. S. railways; 80 miles S. of Terre Haute (for location, see

map of Indiana, ref. 8-B). It is in a coal-mining region; manufactures lumber, flour, and tile, and contains 6 churches, graded public schools, electric light, 2 State banks with combined capital of \$34,000, and a semi-weekly and 2 weekly periodicals. Pop. (1890) 2,161; (1900) 2,292; (1906) estimated, 2,600. Bureau of "Democrat."

Sullivan, ALEXANDER MAURICE: journalist and politician; b. at Castleown, Ireland, in 1836; was connected in 1855 with the Dublin *Refugee*, of which he was editor and proprietor until 1876. In 1868 he was indicted for sedition in consequence of articles referring to the Manchester executions, and sentenced to four months' imprisonment. He was returned to Parliament in 1874 in the Home-rule interest, a movement with which he was especially identified. Mr. Sullivan represented the county of Louth till the general election of 1890, when he was elected for Meath. In 1893 he withdrew from Parliament in consequence of ill health. He published several works, among which are *A Visit to the Valley of Wyoming*, a pamphlet descriptive of a tour in America made in 1857, and *New Ireland* (1877). D. at Dalkey, Ireland, Oct. 17, 1884. F. M. Conway.

Sullivan, Sir ARTHUR SEYMOUR: composer; b. in Londondun, May 18, 1842; the son of a teacher of music. He was early trained in the art, singing in the chapel royal when a mere child; at the age of fourteen gained the Mendelssohn scholarship, which enabled him to pursue his studies under the best masters at home and on the Continent. For *The Tempest* of Shakespeare he composed incidental music which was performed for the first time at the Crystal Palace in 1862. He was knighted May 15, 1893. His compositions include overtures, symphonies, songs, and piano music; the operettas *Box and Cox*, *Thespia*, and *Comedians of the Sea*; the cantatas *The Bride of North Valley*, *Kenilworth*, and *On Sea and Land*; the oratorios *The Typhoid Men*, brought out at the Worcester musical festival in 1892, and *The Light of the World*, produced at the Birmingham festival in 1873; and an opera, the libretto by Chorley, entitled *The Nymphs' Necklace*. Sullivan's greatest successes have been made with his comic operas, in which he had the invaluable collaboration of William S. Gilbert, the distinguished playwright. Beginning with *H. M. S. Pinafore* (1878), and followed by *The Pirates of Penzance* (1879), *Palmyra* (1881), *Julianth* (1882), *The Mikado* (1885), also *The Yeomen of the Guard*, *The Gondoliers*, etc., his popularity has been greater, perhaps, than that of any other English composer. He has also written a grand opera called *Ionathor*, which did not prove a success.

Revised by DUNCAN HUGH.

Sullivan, RALPH: actor; b. in Birmingham, England, in 1824; made a successful debut on the stage at Cork in 1840, acting thereafter in the principal towns of Ireland, Scotland, and England, and making his first appearance at the Haymarket theater, London, in 1852, as Hamlet. He visited the U. S. in 1857; returned to Great Britain in 1860, and in 1861 made a profitable professional visit to Australia, returning to England in 1863. He subsequently became lessee of the Holborn theater, London, and in 1875 made a second and not very successful visit to the U. S. D. at Brighton, England, May 3, 1891. Revised by B. B. VALENTINE.

Sullivan, FRANCIS STOURTON, LL. D.: lawyer; b. probably in Ireland near the middle of the eighteenth century; became Professor of Common Law in the University of Dublin, and was the author of two legal works of great value, *Historical Treatise on the Feudal Law*, and on the *Constitution and Laws of England* (1772) and *Lectures on the Constitution and Laws of England* (1776). F. S. A.

Sullivan, JAMES, LL. D.: jurist and statesman; b. at Berwick, Me., Apr. 22, 1744; studied law; practiced at Bedford, and in 1770 was appointed king's attorney for York County. As the Revolution approached, he espoused the patriot cause; was a member of the provincial congress of Massachusetts, of which Maine was then a part, and was one of a commission of three who were in 1775 sent on a secret mission to Ticonderoga. In 1776 he was appointed a judge of the superior court, in 1779-80 a member of the State constitutional convention, and a delegate to Congress in 1784-85. He removed to Boston for which he was repeatedly chosen representative in the Legislature; was a member of the executive council and judge of probate in 1787; attorney-general of the State 1790-1807; elected Governor in 1807, and again in 1808. He was the projector of the Middlesex Canal, a member of the American Academy of Arts and Sciences, and for many years president of the Massachusetts

Historical Society. Among his works are *Observations on the Government of the United States* (Boston, 1791); *History of Maine* (1795); *Review of the Causes of the French Revolution* (1798); and *History of Land Titles in Massachusetts* (1801). D. in Boston, Dec., 1808. See *Life*, with selections from his writings, by his grandson, Thomas C. Amory (2 vols., Boston, 1859).

Sullivan, JOHN, LL. D.: soldier; brother of James Sullivan, jurist; b. at Berwick, Me., Feb. 17, 1740; studied law and practiced successfully; was a member of the first general congress, and in Dec., 1774, led a company which captured a fort near Portsmouth, N. H. In June, 1775, Congress appointed him a brigadier-general, and during the siege of Boston he commanded the left wing under Gen. Lee. In 1776 he commanded the Northern army in Canada, attacked Three Rivers unsuccessfully, and retreating, joined at New York the army under Gen. Washington. On Aug. 10, 1776, he was made a major-general, and in the battle of Long Island commanded temporarily the division of Gen. Greene; was taken prisoner, but soon afterward exchanged; commanded at Trenton and Princeton the division of Gen. Lee, who had been captured; at the battle of Brandywine commanded the right wing of the army, and defeated the British left at Germantown. Transferred in the winter to command in Rhode Island, he laid siege to Newport in Aug., 1778, but the French fleet under d'Estaing failed to co-operate, and he was compelled to withdraw his forces from the island, after defeating the enemy at Butt's Hill, Aug. 29. In the summer of 1779 he marched against the Indians of the Six Nations, defeated them and their Tory allies, and laid waste the country to prevent their return. Shortly after, he resigned from the army, and in 1780 was again a member of Congress. Resuming the profession of law in New Hampshire, he was attorney-general 1782-86, and president of the State 1786-89; in 1788 his exertions secured the adoption of the Constitution. In Oct., 1789, he was appointed U. S. district judge of New Hampshire. D. at Durham, N. H., Jan. 28, 1795.

Sullivan's Island: a long, narrow island in Charleston co., S. C.; 6 miles from Charleston, and on the north side of the entrance to Charleston harbor. It is the site of FORT MOULTRIE (q. v.), and is a fashionable resort for sea-bathing. There are many summer residences. The island is connected with Charleston by steam-ferryboats, which convey some 200,000 passengers annually. The island is 6 miles long, and is separated from the mainland by a tidal channel.

Sullivant, WILLIAM STARLING, LL. D.: botanist; b. near Columbus, O., Jan. 15, 1803; graduated at Yale College in 1823; took charge of the extensive landed estates left by his father, and devoted himself with great zeal to botany, making the mosses a special subject of study. He published *Catalogue of Plants Native or Naturalized in the Vicinity of Columbus, Ohio* (1840); *Musci Alleghanienses*, to produce which he made a journey from Maryland to Georgia (1845); *Musci and Hepaticæ of the United States East of the Mississippi River* (1856); *Mosses brought Home by Wilkes's Exploring Expedition* (1859); *Mosses and Hepaticæ, collected mostly in Japan* (1860); *Musci Cubenses* (1861); *Icones Muscorum* (vol. i., 1864; vol. ii. (posthumous), 1874); and in conjunction with L. Lesquereux, two series of *Musci Boreales Americani*. D. in Columbus, Apr. 30, 1873.

Revised by CHARLES E. BESSEY.

Sul'ly, JAMES, M. A., LL. D.: psychologist; b. in Bridgewater, Somersetshire, England, Mar. 3, 1842; educated at Taunton, London, and Göttingen; was lecturer in College of Preceptors, London, until 1892, when he became Professor of Philosophy in University College, London. His principal works are *Sensation and Intuition* (London, 1874); *Pessimism* (London, 1877); *Illusions* (London, 1881); *Outlines of Psychology* (London, 1884); *The Teacher's Handbook of Psychology* (London, 1886); *The Human Mind* (London, 1891).

J. MARK BALDWIN.

Sully, st'lee', MAXIMILIEN DE BÉTHUNE, Baron of Rosny, Duke of: chief minister of Henry IV. of France; b. at Rosny, department of Seine-et-Oise, Dec. 13, 1560, of a Protestant family; was from his eleventh year educated with Henry of Navarre; accompanied him through his shifting fortunes at the court and in the camp, and became his Minister of Finance and chief adviser in all public and private affairs when he ascended the throne under the name of Henry IV. A skillful administrator rather than a statesman, he made no radical changes, but contented himself with

improving the efficiency of the existing system. His chief work was the reform of the finances, which were in a disorganized condition, and managed in such a manner as to invite fraud and corruption. By enforcing a proper system of auditing accounts and by insisting that the levy of all sums should be authorized by the Government, he did away with illegal taxation, saved France more than 120,000,000 francs annually, and amassed a reserve of 80,000,000 livres. His economical views were characteristic of his time; he considered agriculture as the only productive source of the wealth of a nation, but his policy had the advantage of making France independent of foreign nations for the prime necessities of life, at a time when she was on the point of entering upon a long period of war. After the assassination of Henry IV., he resigned his offices and retired into private life. D. at Vieillebon, Dec. 22, 1641. Of his *Mémoires*, two volumes were published by himself in 1634, and two more in 1662 by Jean le Laboureur; translated into English by Mrs. Lenox (1834).

F. M. COLBY.

Sul'ly, THOMAS: painter; b. at Horncastle, Lincolnshire, England, June 8, 1788; was taken to the U. S. by his parents, who were actors, in 1792; lived in Charleston, Richmond, New York, and finally in Philadelphia; painted Jefferson, La Fayette, Washington crossing the Delaware, Fanny Kemble, Charles Kemble, Mrs. Wood, Cooke the tragedian, and other actors of celebrity. In England he painted a portrait of Queen Victoria for the St. George's Society of Philadelphia. The *Jefferson* is at West Point, the *Washington* in Boston. Sully did not, like Stuart, confine himself to portraiture. D. in Philadelphia, Nov. 5, 1872.

Sulphates: See SULPHURIC ACID AND SULPHATES.

Sulphides, or **Sulphurets** [derivs. of *sulphur*]: compounds of sulphur with metals and other elements more basic or less electro-negative than itself. This class of compounds is probably quite as large in number as the oxides. Indeed, sulphur combines with one element, fluorine, which is not known to combine with oxygen at all. There seems a general strict analogy between sulphur and oxygen in combination, running through very extended ranges of compounds. The sulphides of the metals possessing practical importance will generally be found described under the head of the metal.

Sulphites: See SULPHUROUS ACID.

Sulphocyan'ic Acid, also called **Hydrosulphocyanic Acid** and **Sulphocyanhydric Acid** [(the names being various combinations of) *sulphur* + *cyanic* + *hydrogen*]: a compound of cyanogen, CNHS, analogous in composition to cyanic acid, CNHO, in which the atom of oxygen is replaced by one of sulphur. It occurs in saliva, and in some sulphuretted essential oils of plants, such as mustard and radish. It may be prepared from sulphocyanate of mercury, which is first made by precipitating a mercurous salt with sulphocyanate (sulphocyanide) of potassium, the material of the so-called "Pharaoh's serpents." *Potassium sulphocyanate* (CNKS) is a salt of much interest from being an important and delicate laboratory reagent for ferric compounds, with which all soluble sulphocyanates strike a deep and characteristic blood-red color. The potassium salt is prepared by fusing cyanide of potassium and sulphur and subsequently purifying.

Revised by IRA REMSEN.

Sulphur, or **Brimstone** [*sulphur* is from O. Fr. *soulfre* < Lat. *sulfur*, *sulphur*; cf. Sanskr. *śulvāri*, sulphur; *brimstone* is M. Eng. *brimston*, *bremston*, *brenston*, *bermston*; *brennen*, *bernen*, burn + *ston*, stone]: one of the most important of the elements of matter, very abundantly and almost universally distributed throughout the earth and the sea. It occurs native as a mineral in many countries. It is also found in mineral form as GYPSUM (q. v.) and in a great variety of metallic SULPHIDES (q. v.); also dissolved in the ocean as sulphates. It is an important essential element of the blood, muscles, skin, hair, and other parts of animals, and exists also in some essential components of plants, though not in the woody substance thereof. It is evolved also from volcanoes, both as vapor of sulphur and as sulphuretted hydrogen and sulphurous dioxide, these gases being doubtless products of the action of oceanic water, that has penetrated to the volcanic focus, upon metallic sulphides it finds there. Indeed, it is more than probable that such action is itself one *vera causa* of vulcanicity.

Most commercial sulphur is merely the native mineral purified by fusion or further by distillation and sublimation. In Sicily, where the crude sulphur, mixed more or

ness with other minerals, is very abundant, and for some time the method is often adopted of roasting a portion of the sulphur of the ore, furnishing the heat (not very great in amount) necessary to fuse out and separate the rest of the sulphur. The ore is piled in heaps, sometimes in kilns, so constructed that a portion of it can be set on fire and heat the whole mass throughout to the fusing-point of the sulphur. The latter then collects slowly in liquid form in cavities formed for the purpose, and may be ladled out and sold or refined. The Sicilian sulphur, being free from arsenic, which is the most objectionable impurity liable to occur, is highly prized for making Solignum Aem. (q.v.). Deposits of sulphur are reported in various parts of the U. S. Mining operations have been conducted in California, Louisiana, Nevada, and Utah, but in 1893 the total product was only 1,200 tons (value \$42,000), all from Utah. The refined sulphur (brimstone) of commerce and the putrescent material known as flowers of sulphur are products of distillation and sublimation—operations which are often conducted simultaneously, there being aliphatic condensing-chambers, the first of which being hot condenses liquid sulphur, which is drawn off and cast into sticks or cylinders; while in the second, which is kept cool, the vapor precipitates in the form of "flowers," which are, when freshly prepared, composed of a special allotropic modification of sulphur.

Sulphur is one of those elements most liable to assume allotropic states when isolated. These are characterized by differences of crystalline form or by amorphous character, different relations to solvents, and different densities, but not so much by different colors as in the case of phosphorus, arsenic, and tellurium. Native sulphur often occurs in very beautiful and brilliant transparent yellow crystals, which are orthorhombic in form, with two imperfect cleavages. When molten sulphur cools it takes the crystalline form, the crystals belonging to the monoclinic system. Very beautiful crystals of this form are easily obtained by breaking the crust upon a cooling mass of melted sulphur and pouring out the liquid interior. On breaking the mass after cooling, the cavity will be found filled with slender brilliant prisms. Sulphur on heating passes through a succession of changes, melting at about 120° C. to a thin yellow liquid. If again cooled, it becomes a permanently transparent solid. Above 180° the sulphur becomes thick and viscid, losing its fluidity altogether and assuming a brown color at about 250° C. At 400° the mass again becomes liquid. At 440° C. (822° F.) sulphur boils, forming an orange-yellow vapor. Some of the sulphur-allotropes, including the two crystalline forms above described, are soluble in several liquids, such as bisulphide of carbon, oil of turpentine, and others. The bisulphide-of-carbon solution on evaporation yields beautiful transparent crystals similar to those of native sulphur. Flowers of sulphur are composed of an amorphous soluble modification. Sulphur inflames in air at a remarkably low temperature, about 482° F., burning with blue flame and evolution of suffocating sulphurous oxide, SO₂.

Medicinal Uses of Sulphur.—Taken internally, sulphur produces little effect beyond that of a mild and somewhat laxative. Externally, applied in the form of ointment, it is a powerful parasiticide, principally employed to kill the little insect that produces the itch disease. *Potassium asulphide* is a sharp irritant, and in large dose internally a corrosive poison. It may be used instead of the simple sulphur ointment as a local remedy in itch and in other skin diseases, and dissolved in water as a bath is used in skin disease and in lead-poisoning. In common with other sulphides it is sometimes used as a depilatory.

Revised by J. A. RICHES.

Sulphurets. See SULPHIDES.

Sulphuretted Hydrogen, called also **Hydrosulphuric** [*hydrogen + sulphur*], **Acid**, etc., a gas, H₂S, analogous to water, H₂O. It was first discovered by Ruelle the younger, but Scheele first ascertained its nature and properties. Sulphuretted hydrogen is emitted naturally by mineral springs and from volcanoes, and in combination with ammonia is evolved in the putrefaction of animal and vegetable matters. The smell of rotten eggs and that of a privy, generally attributed to sulphuretted hydrogen itself, are due chiefly to the compound it forms with ammonia or sulphide of ammonium. Artificially this gas is prepared by the action of a dilute mineral acid on certain metallic sulphides, of which ferrous sulphide of commerce is the one generally employed, though the native sulphide of antimony may also be used. If hydrogen gas be passed through melted sulphur this com-

ponent is formed, and a convenient way to evolve sulphuretted hydrogen for laboratory use is to melt together in a flask sulphur and paraffin. When pure, sulphuretted hydrogen is a colorless gas of an odorous odor, somewhat recalling that of bitter almonds, which produces immediate vertigo in the case of some persons and acts as a deadly poison upon some animals even in very small proportion. Many persons will, however, inhale it in diluted form without much apparent effect for a considerable time, so that it can not be regarded as necessarily a dangerous poison in the case of mankind, though the unnecessary inhalation in quantity ought to be avoided. The density of the gas is 1.175, air being unity. Faraday reduced it by compression to a liquid whose density he gives as about 0.9. The solubility of the gas in water is given by Brown as 4.97 per cent. of its volume at freezing, and about 1/2 per cent. at normal temperature. Alcohol takes up about three to four times as much as water. It is combustible, with a blue flame burning in water and sulphurous dioxide. This gas is a very important reagent in the laboratory for precipitating metals from their solutions in processes of analysis and in many processes of preparation of organic compounds in pure state, particularly in cases of organic acids, which are first converted into lead salts to be decomposed afterward by sulphuretted hydrogen.

Revised by J. A. RICHES.

Sulphuric Acid and Sulphates: a compound of sulphur, H₂SO₄, and its forms of combination with metals. Sulphuric acid is called also *oil of vitriol*, from its having been originally obtained by distillation from vitriol, or sulphate of iron. This acid was probably known to the Arabian physicians. Basil Valentine, however, is the first known author who, writing in the fifteenth century, mentions the making of sulphuric acid by distilling from vitriol. The manufacture by burning sulphur, as now practiced, was introduced in England by Dr. Roebuck about 1720. The general method is to burn sulphur, either as brimstone or in the form of metallic sulphides, as pyrites, in a draught of air, which is passed into very large chambers built of metallic lead, where the sulphurous oxide gas formed by the combustion is mixed with steam and a quantity of nitrous fumes evolved from a mixture of saltpetre or sodium nitrate with sulphuric acid. The oxides of nitrogen in the presence of water oxidize the sulphurous acid to sulphuric acid, and are themselves reduced to lower forms which, in the presence of air, are converted into higher oxides, among which is nitrogen peroxide NO₂, and these again react with sulphurous acid, so that the operation of a limited amount of nitrous fumes is continuous, acting as a carrier of oxygen to the sulphurous dioxide without consumption of its own substance. The product precipitates with condensing steam upon the walls and floors of the leaden chambers as diluted sulphuric acid, which is then concentrated to oil of vitriol—*drag*, in pans of lead, and when it has become strong enough to attack these, the boiling down is completed in large stills made of glass or platinum.

Sulphuric acid when fully concentrated has a density at 0° C. of 1.840. It is an oily, colorless, inodorous liquid, which boils at 337° F. and freezes at -31°. It absorbs water rapidly from the air, being one of the most useful agents in the laboratory for drying air and for absorbing moisture from other substances, which are for this purpose simply placed in a confined space with a quantity of oil of vitriol, which, through the medium of the air, will gradually abstract all the moisture from such substances. When mixed with water, great heat is developed.

Nordhausen, or Fuming Sulphuric Acid.—This is the acid obtained by distilling ferrous sulphate. It has the composition H₂SO₄, and is considered by some chemists as containing sulphuric trioxide SO₃ or as H₂SO₄.SO₃, but this seems hardly in accordance with the fact that it crystallizes as a whole in transparent crystals at zero. When gently heated, however, it breaks up into sulphuric oxide, which distills over and condenses as a solid body, and ordinary oil of vitriol, which remains behind in the retort. Its name of fuming acid comes from the fact of its forming white fumes in the air, due apparently to the evolution of vapor of SO₃, even at ordinary temperatures. Fuming oil of vitriol is used in the laboratory for dissolving indigo and as a reagent in gas analysis, to absorb the illuminant hydrocarbons from ordinary coal-gas.

Titrated Sulphuric Acid.—It is very useful in chemical and technical operations to be able to determine the strength of a dilute acid from its density as taken with the hydrom-

eter. The following figures are condensed from tabulated determinations of densities of dilute sulphuric acid by J. Kolb:

DEGREES BAUMÉ.	Densities.	SO ₃ in 100 parts.
1	1.007	0.7
5	1.037	4.7
10	1.075	8.8
15	1.116	13.2
20	1.162	18.0
25	1.210	23.2
30	1.263	28.3
35	1.320	33.9
40	1.381	39.5
45	1.453	45.2
50	1.530	51.0
55	1.615	57.1
60	1.711	63.8
65	1.819	73.2
68	1.842	81.6

Uses of Sulphuric Acid.—Among those materials and products of science and art that constitute the main pillars of modern civilization sulphuric acid occupies incontestably a first rank. Probably none other except iron could be justly ranged with it in this regard. This will appear on a mere enumeration of some of the principal products necessary to human life, health, comfort, luxury, or necessity which are dependent, directly or indirectly, upon sulphuric acid as an essential agent in their production: *soda* from common salt, and through this, *glass, soap, sodium, aluminium, magnesium*; *nitric and hydrochloric acids*, upon which depend the arts of refining gold and silver for money and jewelry, with the *electroplater's* and *photographer's* arts; artificial *mineral waters*; all the *vegetable acids and alkaloids*; *alum*; *ammonia*; *ultramarine*; the *aniline colors*; *bleaching-powder*; *chrome compounds*; *chloroform and ether*; *phosphorus and matches*; *artificial fertilizers*; *kerosene*; and so on.

Sulphates.—Among the compounds of sulphuric acid with metals are many of commercial value and importance which are described under the heads of the different metals. The following is a more complete enumeration:

Aluminium Sulphates.—Of these there are several, some of which occur as native minerals. The normal sulphate is $\text{Al}_2(\text{SO}_4)_3 \cdot 18\text{H}_2\text{O}$, constituting the mineral *alunogen*. The alums (see *ALUM*) are double salts of normal aluminium-sulphate with the sulphates of potash, ammonia, or soda, containing 24 equivalents of crystal-water.

Ammonium Sulphate, $(\text{NH}_4)_2\text{SO}_4$.—A commercial salt of great importance, anhydrous, not deliquescent, made largely from the ammoniacal liquor of gasworks, and used as a fertilizing agent.

Barium Sulphate, the mineral *barite, barytes*, or *heavy spar* (BaSO_4).—Insoluble in water, very heavy; densities, 4.123 and 4.554. The source of most commercial barium compounds. It is ground, purified, and sold largely as a pigment or inferior substitute for white lead.

Calcium Sulphates; the *anhydrite* mineral is CaSO_4 .—It is orthorhombic. Minimum and maximum densities, 2.911 and 3.104. See *GYPSUM* and *SELENITE*.

Cobalt Sulphate ($\text{CoSO}_4 \cdot 7\text{H}_2\text{O}$).—The mineral *bieberite*.

Copper Sulphate ($\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$).—*Blue vitriol*, an important commercial salt. Crystals triclinic.

Iron Sulphates ($\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$).—*Copperas* or *green vitriol*. A large article of commerce. Crystals monoclinic. This is *ferrous sulphate*. *Ferrie sulphate* (normal) is $\text{O}_2\text{S}_2\text{Fe}_2 \cdot 9\text{H}_2\text{O}$, as the mineral *coquimbite*. There are many basic ferric sulphates.

Lead Sulphate (PbSO_4).—The mineral *anglesite*. Splendid orthorhombic crystals. Minimum and maximum densities, 6.2 and 6.42.

Magnesium Sulphate, *Epsom Salt* ($\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$). See *MAGNESIUM*.

Manganese Sulphate ($\text{MnSO}_4 \cdot 7\text{H}_2\text{O}$).—Monoclinic, like green vitriol.

Mercury Sulphates.—Mercurous sulphate is Hg_2SO_4 , and mercuric sulphate is HgSO_4 . The former is insoluble, like calomel or mercurous chloride; the latter soluble, like corrosive sublimate or mercuric chloride. The mercuric salt is obtained by boiling mercury with oil of vitriol.

Nickel Sulphate ($\text{NiSO}_4 \cdot 7\text{H}_2\text{O}$).—Very beautiful green crystals, right rhombic and isomorphous with Epsom salt. This salt, of much commercial importance by reason of its large use in nickel-plating, is liable to contain iron and copper as impurities, both wholly destructive to its usefulness.

Potassium Sulphate (K_2SO_4).—A hard anhydrous salt,

crystals trimetric; minimum and maximum densities, 2.422 and 2.888. Much less soluble than other potash-salts generally. Water at 0° C. dissolves but 8.36 per cent. It is a considerable article of commerce for fertilizing purposes, for which it has great power.

Silver Sulphate (Ag_2SO_4).—Trimetric crystals, turned green by light. Requires as much as 200 parts of cold water for solution.

Soda Sulphate or *GLAUBER'S SALT* (*q. v.*).

Strontium Sulphate (SrSO_4) forms the beautiful mineral *celadine*; trimetric. Densities, minimum and maximum, 3.589 and 3.992.

Uranium Sulphate ($\text{U}_2\text{SO}_4 \cdot 3\text{H}_2\text{O}$).—Small lemon-yellow prisms.

Zinc Sulphate ($\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$), *White Vitriol*, also the mineral species *goslarite*.—Orthorhombic and isomorphous with nickel-sulphate and Epsom salt.

Sulphur forms with oxygen two compounds: sulphur dioxide (SO_2), that combines with water to form *SULPHUROUS ACID* (*q. v.*), and sulphur trioxide (SO_3), that combines with water to form *SULPHURIC ACID* (*q. v.*). Salts of sulphurous acid are called *sulphites*, and salts of sulphuric acid are called *sulphates*. Also there is known in combination sulphur sesquioxide (S_2O_3), which is contained in hyposulphurous acid ($\text{H}_2\text{S}_2\text{O}_4$), whose salts are called *hyposulphites*, and sulphur hexoxide (S_6O_6), which is contained in persulphuric acid ($\text{H}_2\text{S}_6\text{O}_8$), whose salts are called *persulphates*. This sulphuric acid was formerly called *hyposulphurous* or *hyposulphuric acid*, and its salts *hyposulphites* or *hyposulphates*.

Revised by IRA REMSEN.

Sulphuric Ether: See *ETHER*.

Sulphurous Acid: an acid formed when sulphurous dioxide gas is passed into water. A crystalline hydrate, $\text{H}_2\text{SO}_3 \cdot 6\text{H}_2\text{O}$, was obtained by Schönfeld. Sulphurous acid is a strong reducing agent. It deoxidizes iodic, arsenic, chromic, and permanganic acids and gold chloride, precipitating metallic gold from the latter.

Sulphites.—Of these the sulphites of calcium and of sodium only are of much practical interest, they being prepared commercially to some extent for bleaching and for the prevention of fermentation of wines, sirups, and other organic liquids. There are two soda-salts—one neutral, Na_2SO_3 , and one acid, HNaSO_3 . The latter is obtained as a crystalline precipitate on cooling a warm solution of sodium carbonate which has been supersaturated with sulphurous oxide gas. This salt is used as a reagent. Sulphites that contain an additional atom of sulphur are called *hyposulphites*, as sodium hyposulphite ($\text{Na}_2\text{S}_2\text{O}_3$), which is used in medicine for febrile diseases and in dyspepsia. Revised by IRA REMSEN.

Sulphurous Oxide, Sulphur Dioxide, or Sulphurous Anhydride: the gaseous substance (SO_2), formed by the combustion of sulphur in the air. Even in pure oxygen the same compound is formed. It is emitted by volcanoes. It may be obtained artificially, in a pure state, by heating oil of vitriol with some metals, copper and mercury being among these. Sulphate of the metal and water are at the same time formed: $\text{Hg} + 2(\text{H}_2\text{SO}_4) = \text{HgSO}_4 + 2\text{H}_2\text{O} + \text{SO}_2$. It is also obtainable pure by heating together sulphur and sulphure trioxide, SO_3 , in one limb of a sealed U-tube. It then appears as a liquid, condensed by the pressure, in the other limb. Sulphurous oxide is colorless, with the well-known suffocating odor. Bunsen gives its density as 2.2122 (air being 1), and its solubility in water as about 69 per cent. of the volume of the latter at zero, and 41 per cent. at normal temperature. Alcohol at zero takes up nearly five times as much as water. A pressure of about three atmospheres, or the cold of snow and salt, condenses it to a liquid, which produces so much cold in its evaporation as to freeze water when poured upon it. Sulphurous oxide has strong bleaching power over most vegetable colors, and is therefore used for bleaching. See *REFRIGERATING PROCESSES*.

Revised by IRA REMSEN.

Sulphur Springs: city; capital of Hopkins co., Tex.; on the St. L. S. W. and the Sherman, Shreveport, and S. railways; 80 miles E. by N. of Dallas (for location, see map of Texas, ref. 2-1). It is in an agricultural region, and contains Central College (Methodist Episcopal South, opened in 1876), 2 national banks with combined capital of \$200,000, and 4 weekly papers. Pop. (1880) 1,854; (1890) 3,088.

Sulpicia: (1) a Roman poetess, probably the daughter of Servius Sulpicius Rufus, and niece of Messalla, to whom are attributed a group of six charming elegies, describing

several river systems are connected with each other by arms and canals, and on the banks, in the midst of a luxuriant vegetation, stand the towns and villages. The climate varies in the different parts of the island, but is generally healthful, with the exception of the low coast regions to the W. The heat varies on the coast between 82° and 86° F., at an elevation of from 2,500 to 3,000 feet between 64° and 78°; these highlands are known for their healthful climate. The monsoons are not so steady and regular as elsewhere. The dry season lasts N. of the equator from October to May, and S., from the end of April to the end of October.

Natural Products.—The natural productions are more varied and more abundant than those of any other island in the archipelago. Of metals, gold, iron, copper, and tin abound; brown coal occurs, but anthracite is not found. Rice forms the principal food, then sago, beans, and roots (jolicchos, batatas, and dioscereas). The most palatable among the fruits are the mangosteen, durian, rambutan, rambei, pisang, pineapples, etc., many of which thrive only here, and can not be introduced into other countries. Of trees, the species of *Sideroxylon* (justly called *kayu* (wood) *besi* (iron), that is, iron-wood) yield the best wood for ship-building, it being so hard that it blunts the sharpest arrow; teak is not found. The most important plants entering into commerce are cotton, black pepper, caoutchouc, benzoin, gutta-percha, dyestuffs, and camphor, for which the island was celebrated among the ancients. The Dutch have introduced coffee, tobacco, and cacao. The fauna, Indian in its general character, corresponds nearer to that of Borneo than to that of Java. Of mammals there are eighty species, among which are the elephant, rhinoceros, tapir, tiger, panther, and bear; among the ruminants, the *Cervus equinus* is noticeable; among the many species of apes are the orang utan and two gibbons, the siamang (*Hylobates syndactylus*) and the wau-wau (*Hylobates variegatus*); the buffalo occurs both wild and domesticated; the horse is small, but vigorous, adapted to a mountainous country.

Population.—The population, which was 2,972,383 in 1892, is chiefly Malayan. There are about 25,000 Europeans, mostly Dutch, some Chinese, and other Asiatic races. Sumatra was the cradle of the Malays as a nation; in the interior they founded the empire of Manang-Kaban, once very powerful. Next to them the Battas are the most important division; they formerly inhabited the country N. of lat. 1° N., but the population of Achin has separated from them, and they themselves have decreased in number, and are crowded together in a small space. The Orang Koabos live in the forests; in physical respects they do not differ from the other inhabitants of the islands, but they are uncivilized, though harmless; they are agriculturists. The Malays are all Moslems. The Battas are fetich-worshippers and addicted to cannibalism—a custom which the Dutch have tried in vain to abolish.

History.—Ptolemy calls the island *Aurea Chersonesus*, the Arabs *Fantaur*; the name *Sumatra* occurs in 1330, used of the city of Samatrah. The Arabs visited Sumatra about 860 A.D.; Islamism was introduced into Achin in 1205; the Venetian merchant Marco Polo landed here in 1290; the Portuguese under Alvaro Talesso in 1506, the Dutch in 1597; an English squadron appeared before Achin in 1602. The Dutch East Indian Company established settlements on the eastern coast in 1618. Great Britain tried to compete, but was compelled in 1783 to return all its possessions in Sumatra to Holland. In 1811 it once more occupied the island, but by the treaty of Mar. 17, 1824, it exchanged all its possessions in the archipelago for the Malayan peninsula, and thus Holland became the only European power holding dominion in Sumatra. Since then the Dutch have been occupied in gradually extending their conquests over the entire island. The last to hold out were some tribes of the Battas in the interior, and about 150,000 of them were yet practically independent in 1895.

Revised by M. W. HARRINGTON.

Sumba'wa: an island of the Sunda islands, Dutch East Indies, E. of Java, between Lombok and Flores. Area, 5,400 sq. miles. It is high, mountainous, and volcanic. The still active volcano Tambora, on the north coast, 8,940 feet high, caused a terrible destruction by its eruption in 1815; the ashes fell in Sumatra, 840 miles distant, and in a large part of the island itself all vegetation was completely destroyed. The sea also rose and swept away men and houses. More than 12,000 people are said to have lost their lives. Another eruption, less destructive, occurred in 1836. The

principal products are gold, sulphur, saltpeter, rice, various kinds of wood, and a fine breed of horses. The inhabitants, 150,000 in number and closely allied in habits and manners to those of Celebes, live in four states which are under Dutch authority.

Revised by M. W. HARRINGTON.

Sumbul [from Pers. and Hind. *sumbul*, spikenard]: an umbelliferous plant, the *Ferula sumbul*, indigenous to certain parts of Central Asia. It was originally thought to possess the properties of musk, and to be a nervous stimulant, or, more properly, a drug to "steady" the nervous system. In reality it is of very little value, but is popular with some physicians, who give it to nervous women in association with more powerful remedies. H. A. HARE.

Sumerians: the people who are believed by most Assyrian scholars to have occupied Babylonia before the Semites appeared in that region; to have invented the cuneiform script; and to have been the teachers of the Semites, by whom they were finally displaced or absorbed. It would seem that there were two branches of this people—the Sumerians and the Akkadians. To designate the whole people, sometimes one name, sometimes the other, and sometimes the compound name, is employed. In the Sumerian-Akkadian language are written some of the oldest inscriptions from Babylonia, like those discovered by de Sarzec at Telloh. There are also many bilingual productions of a later date, notably from the library of Assurbanipal. These are mainly grammatical, lexical, magical, ritual, or religious in content. The language seems to have become a sacred tongue, like the Latin of the Middle Ages. While this account represents the prevailing view, it must be added that several eminent scholars, in particular Joseph Halévy in France and Friedrich Delitzsch in Germany, deny in toto the existence of a Sumerian-Akkadian people or language. (Cf. J. Halévy, *La prétendue langue d'Accad*, etc. (Paris, 1875); J. Halévy, *Recherche critique sur l'origine de la civilisation babylonienne* (Paris, 1876); F. Delitzsch, *Assyrische Grammatik* (Berlin, 1889), § 25. On the other hand, cf. E. Schrader, in *Zeitschrift der deutschen Morgenländischen Gesellschaft*, xxix., 1-52 (1875); P. Haupt, *Akkadische und Sumerische Keilschrifttexte* (Leipzig, 1881-82); P. Haupt, *Die Akkadische Sprache* (Berlin, 1883).) These scholars maintain that in the so-called Sumerian or Akkadian we have not a language different from Assyrian, but genuine Assyrian in archaic form, or written in a hieratic script. The question is not one of linguistics merely, but it involves the origin of the Babylonian culture. It can not be considered definitely settled so long as the lack of agreement among specialists prevails. The vast majority of Assyrian scholars, however, feel no doubt as to the reality of the Sumerian-Akkadian language and people, as A. H. Sayce, in *Hibbert Lectures for 1887*, pp. 415-436, while others hold themselves neutral, as Tiele does in his *Babylonisch-Assyrische Geschichte*, pp. 58-71.

D. G. LYON.

Sumeru: See MERU.

Summary Proceedings: in a general sense, any legal proceedings, or proceedings before a judicial tribunal, which are of a summary and peremptory nature, that is, those which are short and simple, and ordinarily dispense with the aid of a jury. Such proceedings, except perhaps in cases of contempt, can be instituted only under express authority of statutory laws, which, being in derogation of the common law, must be strictly construed.

The ordinary purposes for which summary proceedings are resorted to are: (a) Ejectment of a tenant for non-payment of rent, or for holding over his term. Authority to bring these proceedings was first granted in England by the Statute of Laborers, followed by others down to the Summary Act of 1879, which greatly extended the power, and in the U. S. it has been granted to a greater or less extent by the statutes of the various States. (b) For the recovery of debts due the state of the U. S. from a collector of taxes or revenue. (c) For the punishment of the contempt of court. (d) For the punishment of many minor offenses, violations of municipal ordinances, etc., which may be proceeded against without a jury; while in respect to others, the constitutional requirements as to due process of law are satisfied if a trial by jury in an appellate court is accorded the accused.

In the U. S. statutes authorizing summary proceedings are unconstitutional and invalid when they conflict with the constitutional provisions requiring that a trial by jury shall remain inviolate. Such provisions as to the right of trial by jury did not extend the right, but prevented its being abridged. The offense to be punishable by summary pro-

summitage must be petty or trivial, and not of a serious character affecting the public at large; nor on the right of appeal be done away with. They are usually such offenses as were punished by fines, though in some cases by short terms of imprisonment. Violations of municipal ordinances are not strictly criminal in nature, but they are generally undeniably punishable.

The procedure is statutory, and the violator must be strictly complied with.

See *McAdams on Landlord and Tenant*; *Dillon's Law of Municipal Corporations*; *Stephen's History of the Criminal Law of England*; *Cooley's Constitutional Limitations*.
P. THOMAS ADAMS.

Summer-duck: See WOOD-DUCK.

Summers, Thomas Osborn, D. D., LL. D., clergyman and author; b. near Corfe Castle, Isle of Purbeck, Dorsetshire, England, Oct. 11, 1812; removed to the U. S. 1830, and prepared for the ministry; was "scholastic on trial" 1850 the Baltimore Conference of the Methodist Episcopal Church in 1845; aided in organizing the Texas Conference Dec. 1849; was transferred to the Alabama Conference; became assistant editor of *The Northern Christian Advocate*, Charleston, S. C., 1846; was secretary of the Louisville convention in 1845, at which the Methodist Episcopal Church South was organized; compiled hymn-books for the connection; was the general book-editor of the Church from its organization; founded and edited for four years *The Sunday-school Visitor*; removed to Nashville in 1855, the publishing-house being there located; edited *The Quarterly Review of the Methodist Episcopal Church South*; revised and edited hundreds of books for the Church. Dr. Summers was the author of *Commentaries on the Gospels, the Acts, and the Epistles of the Methodist Episcopal Church South* (6 vols.); a *Treatise on Baptism, on the Holy Spirit, The Sunday-school Teacher, or the Catechist's Office of the Church; Sermons, Months, and Days; Talks Pleasant and Profitable; Refutations of the Theological Works of Prince* (not answered in Bishop Watson's *Apology*); *The Golden Censer, an Essay on Prayer*, with a collection of forms for all occasions; and of minor works. He returned Feb., 1862, to Alabama; in 1866 was re-elected general editor, and editor of *The Sunday-school Visitor*; became also editor of *The Christian Advocate*; was Professor of Systematic Theology in Vanderbilt University and dean of the theological faculty, and ex-officio pastor of that institution. D. at Nashville, Tenn., May 8, 1882. See his *Life*, by O. P. Fitzgerald (Nashville, Tenn., 1884).
Revised by A. OSBORN.

Summerside: port of entry in Prince County, Prince Edward island (see map of Quebec, etc., ref. 1-B). It is the second town in size in the province, and has a good harbor, rather difficult of access, a large export trade, considerable ship-building, a public hall, and several manufactures. Pop. (1901) 2,882.

Summers' or Somers's Islands: See BERMUDA ISLANDS.

Summerville: town; Berkeley co., S. C.; on the S. C. and Ga. Railroad; 22 miles N. W. of Charleston (for location, see map of South Carolina, ref. 7-P). It is a noted winter resort for invalids, on a pine-clad ridge extending from the Cooper to the Ashley rivers, and contains several hotels and boarding-houses, brick-works, sawmills, and a weekly newspaper. Pop. (1880) 698; (1900) 2,210.

Sumner, Charles: scholar and Senator; b. in Boston, Mass., Jan. 6, 1811, educated at the Boston Public Latin School and at Harvard College, where he graduated in 1830. He was a recluse and studious boy, seldom joining in any amusement or athletic games; and this mood lasted through his college years. Though a diligent student, he gave more attention to general literature than to the special studies of the university. After his graduation he gave a year to science, belles-lettres, history, and art. In 1831 he joined the Harvard Law School, then under the charge of Judge Story, and entered on his studies with enthusiasm, renouncing all other subjects, and giving himself, without any relaxation, to a profound study of law. This devotion gained him the warm friendship of Story, who treated him as a son. Admitted to the bar in 1834, he visited Washington with such warm letters of introduction from Story as secured him the friendship of Kent, Horace Binney, Judge Marshall, and others, who frankly expressed their wishes that before long he should find his place on the bench. Appointed by Story reporter to his circuit court, he published three volumes of Story's *Decisions*, and often supplied his place as lecturer at

the law school, where he was himself lecturer from 1837 to 1837 and in 1842. In 1838 he edited *Barry's Admiralty Treatise*. In 1837 he went to Europe with numerous letters of introduction; was received with most flattering attention, and became personally acquainted with almost every leading man and woman in Europe. While his days were passed in society and galleries, his nights were spent in study; for he early learned that almost irresistible power of working which distinguished him through life. Returning in 1840 from Europe, he again opened a law office, and, with J. C. Perkins, edited twenty volumes of *Vane's Reports*. It was during this labor that his health broke down, and an illness followed which nearly proved fatal. He could have had, after Story's death (1845), his professorship at the law school, but declined it. In 1845 he was chosen by the city of Boston to pronounce the Fourth of July oration, and took for his subject the *True Freedom of Nations*. This was a plea for peace, and was bitterly-cried at home, though welcomed abroad, and pronounced by Calhoun "the most noble contribution made by any modern writer to the cause of peace." His protest against war he repeated frequently in later years.

Favorite as he had been, and great as was his promise at the bar, his decided anti-slavery position created a resolution to crush him socially and professionally. This hostility pervaded Boston society, her merchants, and the Suffolk bar till the civil war broke out. Sumner valued his social position very highly. He had not inherited it, but had himself achieved it. It is unpeakably in his credit that, when he saw this long-coveted and hardily earned distinction and all his professional prospects crumbling around him, though too tender perhaps of praise and keenly sensitive to blame, he never retreated an inch or remodeled a phrase to regain his place or conciliate opposition. From this moment, however, he was recognized as the leader of the young men of the Commonwealth, and bidden in their hearts. No matter that in after years the Legislature censured, the press abused, and politicians criticized him. He always had, to the day of his death, the hearty, entire, steadfast, and loving confidence of the young men of Massachusetts. This explains his strength and influence in years when, judging of public opinion by the ordinary signs, he seemed to have lost his hold and to be near defeat.

In 1849 he maintained before the Supreme Court of Massachusetts the unconstitutionality of separate schools for whites and blacks. The decision was against him. In 1851, by a coalition between Free-Soilers and Democrats, he was elected Senator of the U. S., the first civil office, and the only one, he ever held. There were twenty-six ballots, and the struggle lasted three months. He took his seat Dec. 1, 1851. Once in the Senate, the force of his will, the almost entire devotion of his time to one cause, the aggressive attitude he took, and the vigor and ability of his innumerable assaults, made him indisputably the leader of the political anti-slavery movement.

In Aug., 1852, he began his congressional assault on slavery by an argument for the repeal of the Fugitive Slave law, entitled *Freedom National—Slavery Fugitive*. This phrase became the watchword of his party, and gave the key to most of his later arguments. In May, 1856, he made one of his ablest speeches, *The Crime against Kansas*, advocating the admission of that State to protect it from slavery. His comments on the conduct of several Senators who had taken a part in the debate, especially Butler of South Carolina, Douglas of Illinois, and Mason of Virginia, and his indignant reply to their personal attacks on himself, led to a scene which Sir George C. Lewis characterized as "the beginning of the civil war." On May 22, 1856, Preston S. Brooks, a nephew of Senator Butler, and one of the Representatives from South Carolina, approached Sumner while writing at his desk in the Senate chamber and struck him, without warning, repeatedly over the head with a heavy cane. Sumner, blinded by the blows, strove to rise and free himself from the restraint of the desk. He succeeded in wrenching it from the floor, to which it was screwed, but fell unconscious from the repeated blows. The indignation at the North was wild and hot, but while Massachusetts and the North generally thrilled with indignation, leading citizens of Boston refused to take part in meetings called to protest, and when Sumner returned to Boston, Nov. 3, 1856, though received by crowds in the streets and by the State authorities, the windows of every house in Beacon Street, through which he passed, except those of Prescott and Sumner Appleton, had their blinds closed to show indifference or contempt.

His injuries proved more serious than was at first supposed. Illness detained him nearly four years from Congress, with the exception of one brief attempt in the winter of 1857-58 to attend the Senate sessions, to which he found himself unequal. Two visits to Europe, rest, and the best medical skill of both hemispheres enabled him at last to resume his seat on Dec. 5, 1859. On Jan. 13, 1857, during his illness, he had been elected unanimously by the Senate, and almost unanimously by the House of Representatives of Massachusetts, to the senatorship. Again in Jan., 1863, and subsequently in 1869, he was re-elected, passing the last twenty-three years of his life in the Senate.

His attention was by no means given exclusively to slavery. His speeches cover all topics of national importance, and are always able. He took a leading part in all great debates. His speech in Jan., 1862, advocating the surrender of Mason and Slidell, taken from the British mail-steamer Trent, is a masterly exhibition of maritime law, and did much to reconcile the republic to that distasteful course. His speech on the Alabama claims in 1869, bitterly offensive to all his English friends and severely criticised by John Bright, was undoubtedly a fair representation of opinion in the U. S., and was the basis of final settlement. His addresses on the constitutional law respecting seceding States, on reconstruction, the war powers of the Government, international relations, internal improvements, etc., exhaust the subjects of which they treat. His sketches of Story, Allston, Granville Sharpe, Lincoln, and Lafayette show rare powers of portraiture. His articles on *White Slavery in the Barbary States*, *Prophetic Voices concerning America*, and other literary efforts, show good taste, ingenious research, and exact scholarship.

Worn down by the labor and excitement of the session, and by a return of the illness which Brooks's assault produced, he again sailed for Europe on Sept. 5, 1872, returning in November. In May, 1872, he had moved in the Senate that the names of victories in the civil war should not be inscribed on the regimental flags. On Dec. 2, 1872, the first day of the session, he again introduced a similar resolve to the Senate. For this he was censured by the Legislature of Massachusetts Dec. 18, 1872. This was rather a political trick than any real expression of Massachusetts feeling. The censure was rescinded the last month of his life. During this session of 1872-73, and the following one, he gave most of his time to his Civil Rights Bill, which puts the Negro on the exact level of the white in respect to inns, juries, schools, churches, public conveyances, and all civil privileges. His health was much broken, however, and an attack of his old malady, agony of the chest, in the Senate Mar. 10, 1874, proved fatal in his own house at Washington on Mar. 11, 1874. Almost his last words were addressed to Judge Hoar: "Take care of my Civil Rights Bill."

His natural powers were not of the highest order. "Industry was his talisman." He knew how to work, and had, as he said of Story, "the genius for labor." In mind he was more like Story, trained to exhaustive research and clear statement, than like Kent and Marshall, born lawyers. In preparing to write or speak he ransacked libraries, laying under contribution all ages and tongues. He had read everything and listened to everybody. His memory never lost a phrase or a fact he had once heard, and could always recall it at the right moment. His wealth of illustration was no effort, but the natural action of a full and ready mind. When first in the Senate his speeches were carefully prepared and written out. It took him five to seven years to acquire the power of extemporaneous debate; but to the last he usually wrote out his speeches. It has been generally supposed he was a mere scholar, fit only for investigation or debate. In truth, no man in Congress was more methodical, exact, painstaking, prompt, and efficient in attending to the details of business pertaining to his office. His eloquence belongs to the school of Burke, whom he liked to be thought to resemble, as indeed he did in features. His speeches had more learning than Burke cared to show, but in wealth of illustration, gorgeous rhetoric, lofty tone, and a "gigantic morality which treads all sophistry under foot," the resemblance was close. His real power lay in the sincerity and fiery enthusiasm of the speaker, whose whole soul freighted his words, and in the fact that there was "always a man behind the speech." He did not know what fear was. Alone in Baltimore on Apr. 18, 1861, he yielded nothing to that mob which the day after shot down the Massachusetts troops. For ten years he walked Washington streets, his life constantly threatened, and well knowing that if a fanatic's or drunkard's hand took

his life the assassin would not only be sheltered by the power of ten States, but petted and applauded as a champion. When he entered the Senate, free speech could not be said to exist there. To him, as much as to any man, was due the breaking of that chain. Sumner was exact in all etiquette, careful in dress, fond of society, easy of access, and had always time for every comer, his hours of study running to midnight and long after. His manner was always courteous, but in his last years had a marked tenderness. To the very last day of his life he was a loving student of the classics of all languages; a "bite of the classics" being his preparation for bed somewhere about two or three o'clock in the morning. He cultivated art, and was a diligent collector of autographs, pictures, rare books, bronzes, and other objects of *virtu*, most of which he bequeathed to the Art Museum of Boston and to Harvard College. To the college library he also gave half of his estate. He was married Oct. 17, 1866, to Alice (Mason) Hooper, widow of W. S. Hooper, of Boston. They separated very soon, and he was divorced May 10, 1873. His complete works were published in 15 volumes (Boston, 1870-83). Eleven of the volumes, with copious notes, were published under his own supervision. For full details of his life, see Pierce's *Life of Charles Sumner* (4 vols., Boston, 1877).

WENDELL PHILLIPS.

Revised by C. K. ADAMS.

Sumner, CHARLES RICHARD, D. D.: bishop and author; b. at Kenilworth, Warwickshire, England, Nov. 22, 1790; educated at Eton and Cambridge (B. A. 1814); took holy orders; became curate of Highclere 1816; librarian and historiographer to George IV. and chaplain to his majesty's household at Carlton House, London, and rector of Abingdon—all in 1821; was made prebendary of Worcester in 1822 and of Canterbury in 1825; dean of St. Paul's and Bishop of Llandaff 1826; in 1827 was transferred to the more important see of Winchester, which he resigned in 1869 on account of the infirmities of age. He published *Praelectiones Academicæ Oxon. habitæ* (London) and the *Ministerial Character of Christ Practically Considered* (1824), besides several *Charges*, and edited in the original and translated the long-lost Latin manuscript of Milton, *De Doctrina Christiana* (1825), which gave occasion to Macaulay's brilliant essay on Milton. He was a brother of John Bird Sumner, Archbishop of Canterbury. D. at Farnham Castle, Surrey, Aug. 15, 1874. His *Life*, by G. H. Sumner, appeared in 1878 (London).

Revised by S. M. JACKSON.

Sumner, INCREASE, LL. D.: jurist; b. at Roxbury, Mass., Nov. 27, 1746; was admitted to the bar in 1770, and began practice in his native town; was representative in the Legislature 1776-80, State Senator 1780-82, associate judge of the Supreme Court 1782-97, Governor of Massachusetts 1797-99, and in 1789 member of the convention for the adoption of the U. S. Constitution. D. at Roxbury, June 7, 1799.

Sumner, WILLIAM GRAHAM, LL. D.: economist; b. at Paterson, N. J., Oct. 30, 1840; prepared for college at Hartford (Conn.) grammar school; graduated at Yale College 1863; traveled in Europe, residing at Geneva during winter of 1863-64; studied philosophy at the University of Göttingen 1864-66, and at Oxford, England; was tutor in Yale College 1866-69; took orders in the Protestant Episcopal Church Dec. 29, 1867; was for a time assistant minister of Calvary church, New York; appointed Professor of Political and Social Science at Yale College 1872. Among his works are a *History of American Currency* (1874); *Collected Essays in Political and Social Science* (1885); *Protectionism, the System which teaches that Waste makes Wealth* (1885); *The Financier and Finances of the American Revolution* (1891); and *Robert Morris* (1892).

Sumptuary Laws [from Lat. *sumptuosus*, deriv. of *sumptus*, expense, extravagance]: laws which seek to restrict and regulate private expenditures, and generally are aimed at extravagant outlays for food, for clothing, or for funerals. Such laws were enforced, in past centuries, by every nation of the Old World, and have been indulged in, to some extent, even by the modern States of North America. For example, Massachusetts thought it necessary at one time to regulate by legislation the cost of funerals. These laws have flourished most abundantly in the periods of transition from semi-barbarism to civilization. Witness the legislation of Lycurgus and of Solon, in Greece, that of the Roman republic especially from the Twelve Tables to the second century before Christ, and that of modern European states during the thirteenth, fourteenth, and fifteenth centuries.

The reason for this is twofold: First, public opinion among the governing class does not keep pace with the rapidly increasing conveniences and refinements of life, but insists upon tabulating them as conducive to ostentation. Second, the state has unlimited confidence in its strength and wisdom and undertakes to guard its subjects with paternal care. Some of the most interesting specimens of sumptuary legislation in modern Europe are found among the laws of Frederick II. in Italy, of Edward III. in England, and of Philip IV. in France. One of these statutes (10 Ed. III., c. 5), ordaining that no man should be served at dinner or supper with more than two courses, except upon certain great holidays, when he might be served with three, was not repealed until the nineteenth century.

This kind of legislation is condemned generally by modern political writers. Adam Smith declares, "It is the highest impertinence and presumption in kings and ministers to pretend to watch over the economy of private people and to restrain their expenses, either by sumptuary laws or by prohibiting the importation of foreign luxuries." Richter, however, contends that while such laws are at present useless or harmful, they have proved salutary at times, citing in support of his view the laws of Florence in the fifteenth century against extravagant outlays upon personal pleasures, which, he believes, tended to promote indolence in the nobler luxury of building churches and palaces, of collecting libraries, and of encouraging artists; and the laws of the Roman empire which drove the most vicious forms of vice under cover.

During the sixteenth and seventeenth centuries the nature of sumptuary legislation underwent a change. It was enacted not so much from a benevolent regard for the spendthrift as from commercial and police considerations. English legislators, for example, prohibited the wearing of silk on garments, not with a view to limit personal expenditures, but to promote domestic manufactures of wool. In various countries laws assuring a sumptuary appearance were passed for the purpose of maintaining class distinctions. The latest piece of true sumptuary legislation in Great Britain is the Scotch luxury law of 1621. In our day the bare sumptuary is often applied to laws curtailing or prohibiting the liquor traffic. They are dealt with by the courts, however, as police regulations. Under the Federal and State constitutions of the U. S., with their special guarantee of individual liberty, it is held that the habits, occupation, food and drink—the life of the individuals—are several matters for his own determination. They can be abridged by the majority of the people, speaking through the Legislature, only when the public safety, the public health, or the public protection requires it. The constitutional guaranty of life, liberty, and the pursuit of happiness can be limited only by the absolute necessities of the public. *Infamousness Doctrine Case*, 25 Kan. 751, 755; *Mugler vs. Kansas*, 123 U. S. 623.

FRANCIS M. HODGINS.

Sumter, city; capital of Sumter co., S. C.; on the Atlantic Coast, the Cent. of S. C., and the Charleston, Sumter and S. railways; 40 miles E. by S. of Columbia; 33 miles N. by W. of Charleston (for location, see map of South Carolina, ref. 5-17). It is in an agricultural and a tobacco and truck raising region; ships annually 25,000 bales of cotton; and contains 4 churches for white people and 4 for colored, 5 public-school buildings, 2 academies for young ladies, 2 planing-mills, cotton, telephone, and sack and blind factories, improved system of water-works, electric lights, a national bank with capital of \$75,000, a State bank with capital of \$75,000, and 6 newspapers. Pop. (1890) 3,611; (1896) 4,865; (1898) 5,812.

EDWIN DE HERAULT.

Sumter, Thomas (soldier); b. in Virginia in 1754; removed in early life to South Carolina; participated in the Cherokee war, and was a prominent actor in the events which preceded the Revolution; was appointed lieutenant-colonel of the Second Regiment of riflemen in Mar., 1776, of which he became colonel; served in the interior of the State until the fall of Charleston; went to North Carolina and raised a large force, with which he defeated July 12, 1780, a force of British and Tories; made an unsuccessful attack on the post at Rocky Mount Aug. 1, but Aug. 4 defeated and routed the Prince of Wales regiment at Hanging Rock, and dispersed a large body of Tories; was defeated and routed by Tarleton on the 16th at Fishing Creek; gained a victory at Broad river Nov. 12, and on the 26th defeated Tarleton at Mudasawka, and was severely wounded; had previously been appointed brigadier-general of South

Carolina militia in Jan., 1781; received a vote of thanks from Congress for his valiant services; having raised three regiments of rangers, incorporated with Marion, Pickens, and other partisan leaders, was member of the convention which adopted the Federal Constitution; was member of Congress 1791-93 and 1797-1801, U. S. Senator 1801-08, and U. S. minister to Brazil 1809-11; D. at South Mount, near Camden, S. C., June 1, 1832.

Sumner, Fort: see FORT SUMNER.

Sun (U. Eng. *sun*; *son* (U. H. *son*), *son* (Mod. Germ. *sonne*); Ital. *sonno* (U. *sonno*, *sonno*; of, with different suffixes); U. Eng. *son*; Goth. *son*; *son* (Goth. *son*); Lat. *sol*; *sol* (U. *sol*), the most important body in the universe, next to the earth on which we dwell. It is the great center around which all the planets of our system revolve, and without its vivifying influence the whole earth would speedily be enveloped in a mantle of ice, in which no living being could exist. Yet to the question what the sun is, science can not as yet return an entirely satisfactory answer. The ancients knew that it was a shining sphere, and it is now known to be a very hot body; what is known more than this consists rather of fragments than of a well-rounded body of knowledge. Numerous though the fragments are, it is true that modern science has raised more questions about the sun than it has conclusively answered.

Beginning with certain particulars on which there is exact knowledge, it may be stated that the mass and volume of the sun are enormous compared with those of the earth, and that nature here conducts her operations on a scale of which we can form no conception. In volume it is more than a million times that of our earth; its mass more than 333,000 times. Its density is about one-fourth that of the average of the materials which make up the earth, and therefore only about half as much again as that of water. Its mean distance from us is 93,000,000 miles; its diameter 866,000 miles. The force of gravity on its surface is twenty-seven times what it is on the earth. Under such circumstances a man attempting to stand up would be instantly crushed to death by his own weight. High mountains could scarcely exist, because they would be flattened out by the pressure, and vegetation of the sort familiar to us would not be possible.

Like the earth and planets, the sun rotates from W. toward E. on an axis nearly perpendicular to the ecliptic. It has therefore two poles, where the axis intersects its surface, and an equator of its own. The period of rotation is about 26 days. A curious circumstance is that the equatorial regions rotate in less time than those nearer to the poles, the range being perhaps from 25 to 28½ days.

Temperature and Physical Constitution.—The flood of heat which the sun sends us at the enormous distance indicates that the matter composing it is intensely hot; but estimates of the actual temperature have differed widely. It appears higher than any that we have yet produced, even in the electric arc; probably more than 10,000° F. This statement applies to the photosphere, or visible surface of the sun; the great invisible interior must be at a much higher temperature. There must be a constant intermingling of matter between the interior and the surface, else the latter would speedily cool off under the influence of its rapid rotation. Consequently the interior must be, at least in the great mass, either liquid or gaseous. The best sustained view at the present time is that at such a temperature as that within the sun, no permanent chemical combination is possible. There can be only an indiscriminate mixture of elements; for example, a mixture of oxygen and hydrogen, instead of water. Moreover, the distinction between a liquid and a gas becomes obliterated under the unusual effect of the temperature and the pressure. We must therefore regard the sun as a mass of gas, condensed nearly to the density of a liquid by the pressure of its own mass. The visible photosphere is, indeed, sometimes supposed to be wholly or partially solid. This is a point not yet settled. It may be that, under the influence of rapid cooling, the substances which rise to the surface are constantly condensing to solids, and then falling down again are once more melted by the heat of the interior; but it has also been pointed out that a purely gaseous envelope around the sun would increase so rapidly in density toward the interior, owing to the enormous pressure of gravity, that it would present the same appearance that the sun actually does.

Appearance of the Photosphere.—Through a good telescope, under favorable conditions, the photosphere is seen to have a mottled or mottled appearance, looking much like a

plate of rice soup. This appearance probably arises from a constant rising of currents of heated matter from the interior. Although attempts have been made to assign definite shapes to these seeming rice-grains, the writer believes that they are quite irregular, both in size and shape, and have no well-marked outline or distinctive features.

When the apparent center of the sun is compared with the edge of the disk, it is seen to be markedly brighter; this difference can be seen without a telescope, if the sun is examined through a very dark-green or blue glass, so as no longer to dazzle the eye. It is attributed to absorption of the rays by the solar atmosphere, a view which is confirmed by the fact that different rays of the spectrum are absorbed in very different degrees. The absorption is greatest of all in the case of the photographic rays, so that a photograph of the sun will ordinarily show very dark at the extreme limb unless over-exposed at the center. The absorption is less in the visual rays and still less in the heat rays, which shows that as we descend in the spectrum the transparency of the sun's atmosphere to the rays increases.

Solar Spots.—The most striking and peculiar feature of the photosphere is formed by the spots, which may nearly always be seen when the sun is examined with a telescope. They were seen by the earliest telescopes, and have formed a subject of constant study by astronomers ever since. When examined with a high power, and under favorable conditions, a sun-spot is found to possess marked peculiarities

FIG. 1.

of structure. A general idea of the appearance may be formed from Fig. 1. We have in the center a dark portion called the nucleus, or *umbra*, which is commonly of irregular form. The word dark must, however, be interpreted in a relative sense; though apparently dark in contrast with the effulgence of the photosphere, the spot would be intensely bright if isolated. Around this dark center is a gray fringe intermediate in brightness between the nucleus and the photosphere, which is called the *penumbra*. To ordinary examination the penumbra appears to be nearly uniformly gray, but when best seen in a good telescope it is found to have a striated or fibrous appearance, being composed of an immense number of root-like filaments directed from the outside toward the center. Groups of minute specks, brighter than the general surface of the sun, are often seen in the neighborhood of spots or elsewhere and are called *faculae*.

The spots vary in size from the smallest visible points to objects large enough to be seen with the naked eye, and therefore nearly 100,000 miles in diameter. A curious circumstance is that the spots are not seen all over the solar disk, but only near to what, in our globe, would correspond to the tropics. They are most numerous about twenty degrees on each side of the solar equator; they are rarely seen exactly at the equator, and scarcely ever in more than thirty-five or forty degrees of latitude. They frequently appear in groups comprising two or three, and sometimes many more. In consequence of the sun's rotation, each spot is seen to move slowly across its disk, occupying about thirteen days from the time it appears on one side until it disappears on the other, always supposing that it endures as long as this. The duration of a spot is very variable, ranging from a few days to several months.

A view very generally entertained is that the spots are cavities in the photosphere. This was believed because, as the spot approaches the edge of the sun, the umbra is supposed to appear wider on the side toward the sun's limb, which would be the case if it were a hollow cone at which we were looking obliquely. But the figure and size of the penumbra are so irregular that it is not easy to establish such a fact as this, and Schörrer, of Potsdam, one of the industrious students of solar spots, denies that there is any such difference. According to his view, the penumbra is on the same level with the photosphere. Yet another view is that the spots are cooled portions of matter floating, as it were, upon the hotter photosphere. They have also been attributed to down-rushes of matter, carrying the cooler portions near the surface with them. Between these various views it is impossible at present to decide.

Periodicity of the Spots.—It has been well established by careful observation since about 1850, as well as by previous

records, that the frequency of the sun-spots goes through a fairly regular period of about eleven years. In recent years the maxima have occurred about the years 1848, 1860, 1870, 1881, and 1892. The next maximum may therefore be expected about the year 1903 or 1904. During the years of maximum the sun is rarely seen without spots, and generally with a considerable number. During the intermediate years of minima the sun is seen without spots about half the time. The variation does not, however, go on with entire uniformity, the general rule being that the rise from minimum to maximum is more rapid than the fall from the maximum to the minimum. For instance, a maximum occurred about the year 1860, a minimum about 1867, and another maximum about 1870. Thus the number of spots took seven years to fall to a minimum, and only three to rise to a maximum. We also have here an illustration of the irregularity of the period. The interval is not always exactly eleven years, but sometimes a little more and sometimes a little less, varying in an irregular manner. Sufficient data have not yet been accumulated to determine accurately the law of change. It was formerly supposed that the maxima and minima might be associated with the revolutions of the planets, a view which was first suggested by the close approximation of the period of the sun-spots to that of Jupiter, the latter being somewhat less than twelve years; but careful investigation shows that the sun-spot period can not be as great as the period of Jupiter, so that the close approach to coincidence can be regarded only as an accident. The fact seems to be that the variation occurs in consequence of a cycle of changes going on within the body of the sun itself, but of the nature of those changes nothing is known.

The Sun's Surroundings.—The glare of the sun's rays in our atmosphere, even in the finest climates, is such that objects in its immediate neighborhood are ordinarily invisible. But from time to time there are a few rare minutes in which this glare is removed, in consequence of the moon passing over the sun's disk in a total eclipse. The opportunities thus offered for scrutinizing the immediate neighborhood of the sun have resulted in bringing to light a number of singular phenomena, many of which can be seen only during total eclipses. (See CORONA.) It is known that the photosphere is surrounded by a comparatively thin layer of vaporized or gaseous matter, known as the *chromosphere*. Continuous with this layer, and yet possibly having a different origin, are the protuberances, which appear to consist of vast masses of glowing gas ejected from the sun with inconceivable force, the velocity sometimes amounting to 200 miles a second. These protuberances exhibit a great variety of the most fantastic forms, sometimes appearing like immense flames, sometimes like clouds floating above the sun and remaining for hours, or even days, in the same region. It has been noticed that they are more frequently seen in the neighborhood of sun-spots than elsewhere, yet not necessarily over the spots. Some of the forms are shown in Fig. 2, on a scale

FIG. 2.

on which the earth would be represented by a globe of perhaps one-eighth of an inch in diameter.

The coronal light is so much fainter than that of the

perpendiculars that it can not be detected, even by the spectroscopes except during total eclipses. (See ECLIPSE.) It can be plainly seen extending to a distance from the sun, nearly equal to its semi-diameter, but it also shows rays or streamers extending to much greater distances, sometimes a degree more, and therefore millions of miles in extent. The most remarkable feature of its spectrum is a bright line in the green, which was discovered independently by Young and Harkness during the total eclipse of 1860. This line has not certainly been identified as belonging to any substance known to exist on the earth, and the term coronium has been applied to the unknown element which causes it. Repeated study of the corona seems to show that it generally has the greatest extent about the middle latitudes of the sun, and that its structure is of a peculiar filamentous character like that of combed wool. A resemblance of these filaments to the lines of magnetic force has been brought out by Prof. P. H. Bigelow, who has constructed a magnetic or polar theory of the corona, ascribing it to the sun's magnetism. It can not be said, however, that any entirely satisfactory theory of this object has yet been established. Magnetic force may very well account for the structure and appearance, but the great difficulty is how substances of any sort can remain at rest so near the sun, under the enormous gravitating force of the latter. The corona has sometimes been described as a solar atmosphere, but it can not be such in the sense in which we use the term atmosphere. The fact that comets have passed through its substance with a speed of several hundred miles a second, without suffering, so far as could be seen, the slightest retardation or disturbance, shows that there can be in the corona no substance but such as are of the utmost tenuity—particles so light that the thinnest air would be as lead in comparison. It has been suggested that these particles may be held up by electrical repulsion, or that they may be in a state of projection, continually thrown up from the sun and falling back again upon its surface. All these hypotheses are possible, and some may be more or less probable, but no one is yet proved to the exclusion of the others.

Elements which compose the Sun.—A comparison of the solar spectrum with the spectra of the various elements found on the earth shows that the sun is composed very largely of the same substances as the earth. The most thorough comparison of this kind is that of Rowland, which is still in progress. He finds that thirty-six terrestrial elements may be detected in the sun. Of these, calcium, iron, and sodium are among those most strongly marked. The elements not yet detected are mostly those which are found on the earth in comparatively small quantities, such as antimony, arsenic, gold, mercury, etc. The most curious case among the doubtful elements is that of oxygen. It is not yet certainly decided whether the spectrum of the sun does or does not show the existence of oxygen in that body. It is to be remarked that the absence of the lines of an element in the solar spectrum does not prove the absence of that element. The solar spectrum shows only the lines of those elements which are vaporized at its surface; hence if any elements do not come to the surface at all, or do not form a vapor there, they will not show themselves in the solar spectrum. The general result has been summed up by Rowland in the remark that were the earth heated up to the temperature of the sun, its spectrum would probably resemble that of the sun very closely. It is also to be remarked that there are lines in the spectrum of the sun, or of its surrounding atmosphere, which have not yet been identified as belonging to any terrestrial element. Of these the most noteworthy is a line, D_3 , found in the spectrum of the chromosphere and attributed to a non-terrestrial substance which has received the name *helium*. It has been announced by Ramsay (1868), however, that a gas obtained from cleveite, a rare mineral from Norway, shows this line, and therefore may be presumed to be helium. For an illustration of the solar spectrum see the article SPECTRUM.

The question whether the sun affects the earth otherwise than by its light, heat, and gravitation is one with which science is busy, but on which no positive conclusions are yet reached. A relation between the period of the sun and that of the sunspots seems to be not improbable, but the question whether auroras are themselves excited by actions going on in the sun is an open one. This whole class of questions can be settled only by long-continued observation and careful study.

The Sun's Heat.—The question of the permanence of the sun's heat is presented in a new light by these generaliza-

tions of modern science which relate to the conservation of energy. To our ancestors there was no apparent reason why the sun should not continue to light and warm the earth and planets forever; but modern science shows that the radiation of heat from the sun to the earth involves a continuous expenditure of an agent called energy, of which the supply is necessarily limited.

The quantity of heat which is received from the sun has been determined by several experimenters. The recent observations of Langley probably give the most accurate result, which may be expressed in the following way: Let us consider a cubic centimeter of water, that is, a cube about four-tenths of an inch on each side. We may realize this cube in the form of a thin metallic vessel, filled with water. Let this vessel be covered with lampblack, and one side of it be exposed perpendicularly to the rays of the sun. Langley's result is that if these rays reached the earth without being absorbed by our atmosphere, they would, when absorbed by the cube, heat it at a rate of 26° C., or 64° F., per minute. Taking as the unit of heat the quantity which would raise the temperature of 1 cubic cm. of water 1° C., we may say that the sun radiates upon each square centimeter of surface 26 heat units per minute. Imagine a spherical surface surrounding the sun, at a distance equal to that of the earth's orbit. Every square centimeter of that surface would receive this quantity of heat from the sun. We may state this result in another way. If the amount of heat falling on a square centimeter were transformed into a lifting force, without any loss whatever, it would raise a cubic centimeter of water against the force of gravity at the rate of about 4,500 feet per minute. A similar computation shows that the heat which the sun, when near the zenith, radiates upon the deck of a steamship would suffice, could it be turned into work without loss, to drive her at a fair rate of speed.

Considering the sun simply as a hot body, it would be cooled by the heat which it radiates, and calculation shows that the amount of heat radiated would result in a cooling of 5° , more or less, per year, assuming in the specific heat of the substances which compose it. It follows that, in such a case, the sun would cool off entirely in a very few thousand years. As no actual cooling seems to take place, the question arises how the heat is kept up.

Two theories on this subject have been maintained in recent times. One, known as the meteoric theory, is that the countless meteors which are known to be moving in all directions through the solar system are continually falling into the sun and supplying it with the heat generated by the impact. As to this theory it can only be said that it seems impossible that meteoric matter in sufficient quantity could be falling into the sun. The other theory, which is now universally accepted, at least provisionally, by the ablest physicists, is that the heat is kept up by the contraction of the sun's volume as it cools. A very curious result of this contraction was reached some years ago by an American investigator, J. Homer Lane, who showed that as the sun contracted it would actually become hotter, because although heat was lost by radiation, yet, so far as temperature was concerned, this loss would be more than made up by the resulting contraction, so long as the sun remained gaseous. This, however, does not mean that the heat would last indefinitely. After contracting to a certain point the matter composing the sun would necessarily begin to assume a solid or liquid form, and then would rapidly cool off. The available supply of energy would then be exhausted forever, and our system would be overtaken by eternal cold and darkness. Thus the physical conclusion to which we are led by a study of the laws of nature is that the sun, like a living being, must have had a birth and will have an end. From the known amount of heat which it radiates we can even, in a rude way, calculate the probable length of its life. From fifteen to twenty millions of years seems to be the limit of its age in the past, and it may exist a few millions of years, perhaps five or ten, in the future.

These computations have brought the conclusions of physics and astronomy into collision with those of geology. About the middle of the nineteenth century geologists were led by a study of the rocks composing the earth's surface in successive periods of their deposit to conclude that geological processes must have been going on for hundreds of millions of years. It can not be said that a complete reconciliation has yet been reached; but the writer believes that the general tendency of late years has been to shake the confidence formerly felt in the great length of the geological ages.

Connected with and yet apart from this is the question of the invariability of the supply of heat. Can we be sure that this supply has been every year the same during many ages past, and that it will remain unchanged for ages in the future? May it not be that the glacial epoch was due to a diminution of the sun's radiation? May this radiation not increase or diminish in the future to such an extent as to affect seriously the activities and destiny of the human race? These are questions to which the science of to-day can return no positive answer. All that can be said is that during the two or three centuries of accurate observations of temperature and climate there is no evidence of any permanent change. Adding to this the fact that a comparison of the ancient records of the magnitude of the stars with their present magnitudes does not show any evidence of change, and that the sun is undoubtedly a star which is brighter than others because we are so much nearer to it, the conclusion is that there is no reason to apprehend any sudden or rapid changes in the supply of solar heat.

BIBLIOGRAPHY.—*The Sun*, by C. A. Young, in the International Scientific Series, is the latest complete work in English on the subject. Proctor's *The Sun, Ruler, etc., of the Planetary System*, will also be found extremely interesting. A yet more voluminous work is that of Secchi, *Le Soleil* (2 vols., Paris, 1870), which is beautifully illustrated.

SIMON NEWCOMB.

Sun Animalcules: See HELIOZOA.

Sun-bird: any bird of the family *Nectariniidae*, inhabiting a great part of Africa, Southern Asia, and Australasia. Although only distantly related, the sun-birds have a superficial resemblance to the humming-birds, with which they are generally confounded by colonists, in their smallness, slender build, brilliant, often metallic colors, and habits of feeding from flowers, but belong to a different order, the passerines. The tongue is practically tubular and suctorial, although their food consists mainly of insects. Their nests, which are roofed over, are swung from a slender twig or the tip of a leaf; the eggs, generally three in number, are white, plentifully sprinkled with grayish green. There are over 100 species, which have been described in a *Monograph of the Sun-birds*, by Capt. Shelley (London, 1876-80).

F. A. LUCAS.

Sun-bittern: a wading bird (*Eurypyga helias*) of somewhat uncertain affinities, but usually placed in a separate family (*Eurypygidæ*) near the cranes and rails. It is about 16 inches long. The head is black, with a white stripe above and beneath each eye; the balance of the plumage is curiously and elaborately mottled with black, white, chestnut, and various shades of buff and brown. The sun-bittern is found along the banks of rivers in the northern and eastern parts of South America, and feeds on fishes and insects. Its nearest relative is the Kagu (*q. v.*).

F. A. LUCAS.

Sunbury: borough; capital of Northumberland co., Pa.; at the junction of the northern and western branches of the Susquehanna river; on the N. Cent., the Penn., and the Phila. and Reading railways; 54 miles N. of Harrisburg, the State capital (for location, see map of Pennsylvania, ref. 4-G). It is in a lumbering region; is an important shipping-point for coal; and contains the repair-shops of the Phila. and Erie Division of the Penn. Railroad, rolling-mill, organ-factory, saw and planing mills, nail-works, and coffin, table, and sash and door factories, a national bank with capital of \$200,000, a trust and safe-deposit company with capital of \$125,000, and a daily, a monthly, and two weekly periodicals. The borough was founded in 1772; was the site of the Indian village of Shamokin and of Fort Augusta, erected by the provincial government in 1756 as a defense against the French and Indians, the magazine of which is preserved in the Fifth Ward of the borough; and is separated from East Sunbury borough (incorporated in 1891) by a small stream. The interests of the two boroughs are identical. Pop. (1880) 4,077; (1890) 5,930; (1895) estimated, Sunbury, 8,000; East Sunbury, 2,000.

EDITOR OF "SUNBURY DAILY."

Sunda Islands: the chain of large islands belonging to the Malay Archipelago, which, beginning with Sumatra and ending with Timor, separates the Java Sea from the Indian Ocean. The name is derived from the indigenous name of the western part of Java, adjoining the Sunda Straits. See JAVA.

M. W. H.

Sun'darbans, or Sunderbunds: the part of the delta of the Ganges which extends from the Hugli to the Megna. It

has an area estimated at 7,550 sq. miles, and consists of a great number of smaller and larger islands covered with dense forests and infested by tigers and crocodiles. As this tract of land is in the highest degree pestiferous, the Government has taken measures to improve it, or at least make it innoxious, and in many places the forests have been cleared and the ground transformed into fields of rice and sugar.

Revised by M. W. HARRINGTON.

Sunday [O. Eng. *sunmandæg* (*sunne*, sun + *dæg*, day, transl. of Lat. *dies solis*; *dies*, day + *solis*, genit. of *sol*, sun. See SUN); the secular name of the first day of the week, which is held among Christians as a Sabbath, or rest-day, and in remembrance of Christ's resurrection. As soon as the Christian religion was recognized by the state, laws were enacted for the observance of Sunday. Constantine (321) prohibited all business except agricultural labor and all legal proceedings except the manumission of slaves. Subsequent emperors made similar enactments. Theodosius II. (425) forbade games and theatrical exhibitions on Sunday (*Cod. Theod.*, xv., tit. 7). The most strict of these laws is that of Leo and Anthemius (469, *Cod. Justin.*, iii., tit. 12). The laws of Theodoric the Great, several kings of France, and especially Charlemagne (813), prohibited servile work and secular business.

In England Sunday laws were of very early origin. The common law distinguished Sunday from other days by allowing no judicial acts on that day, according to the maxim, *Dies dominicus non est juridicus*. The code of Ina, King of the West Saxons (about 603), punished servile work by fine. Alfred the Great (876) forbade work, traffic, and legal proceedings on Sunday. Similar laws were in force through all the Saxon period, and were often enacted in subsequent reigns. The statute 27 Hen. IV., c. 5, enacts that all fairs and markets on Sundays, except in harvest, shall cease on pain of forfeiture of goods. The statute 5 and 6 Edw. VI., c. 3, makes Sundays, with Christmas, Easter, etc., holy days, but permits work in harvest and in other cases of need. The statute 1 Eliz., c. 2, punishes by fine persons absenting themselves from church without excuse. In 1618 James I. issued his *Book of Sports*, in which he declares certain games, sports, etc., lawful on Sundays after divine service. Charles I. in 1638 reissued the *Book of Sports*. The most important of the English statutes is 29 Chas. II., c. 7, which prohibits all worldly labor or business (works of necessity and charity only excepted), the sale of goods, traveling for purposes of trade, and the serving or executing of any process or warrant, except in case of treason, felony, or breach of peace. The dressing of meat in families and its sale in inns and eating-shops and the crying of milk before nine and after four are allowed. This statute, somewhat modified by subsequent laws, is the present Sunday law of Great Britain, and lies at the basis of the Sunday laws of the U. S.

In France, during the Revolution, when the Christian calendar was abolished and the decade substituted for the week, each tenth day was made a rest-day, and its observance was enforced by a law (17 Thermidor, An VI.) which required the public offices, schools, workshops, stores, etc., to be closed, and prohibited sales except of eatables and medicines, and public labor except in the country during seed-time and harvest. On the restoration of the Gregorian calendar, Sunday was recognized in the *Code Napoléon* (Art. 25, 260). A law of Nov. 18, 1814, prohibited ordinary labor, traffic, etc., and, though declared by the courts in 1838 and 1845 to be still in force, it has been for many years a dead letter. The International Sunday-rest Congress, in connection with the Paris Exposition of 1889, and the Berlin Labor Conference, convened by the German emperor in 1890, gave increased prominence to the question of the legal protection of Sunday rest which had been previously agitated by labor and other associations. Laws restricting Sunday labor and trade to a greater or less extent exist in Germany, Switzerland, Austria, Hungary, Belgium, Holland, Denmark, Sweden, and Norway.

The early English colonists of North America brought with them the observance of Sunday, both as a religious and as a civil institution, and both the religious and secular observance of the day was enforced by laws similar to the English statutes, though modified by the popular feelings and modes of life. The early laws of Massachusetts, Connecticut, Georgia, South Carolina, and Virginia compelled attendance at church, the Massachusetts law (1782) providing that such attendance was not required where there was no place of worship which the person could conscientiously

crusade attend. (The oft-quoted Black Letter (q. v.) of Parliament are a pure fiction, first published in London in 1786 by Samuel Parnis, in revenge for having driven from the colony on account of his obstinate republicanism.) After the establishment of the Federal Government, as the separation between church and state came to be more fully understood and carried out, the earlier Sunday laws were modified in conformity with this principle, and the legislatures and courts have been careful to distinguish between Sunday observance as a religious and as a civil institution, and to enforce only the latter. The existing Sunday laws rest chiefly upon the following grounds: The right of all classes, so far as practicable, to rest one day in seven; the right to undisturbed worship on the day set apart for this purpose by the great majority of the people; the devout respect which should be paid to the religious institutions of the people; the value to the state itself of the Sunday observance as a means of that popular intelligence and morality on which these institutions are conditioned. The Federal Constitution provides that Sunday shall not be reckoned in the ten days within which the President may return any bill; the Federal courts and the offices of the departments are closed; the exercise of the post-office is restricted; no session of Congress is held, and provision is made by act of Congress for the observance of Sunday in the army and navy. Beyond this, Sunday legislation does not come within the sphere of the Federal Government. The constitutionality of all but a very few of the States, like the Federal Constitution, except Sunday in reckoning the time within which the executive may return a bill to the legislature. Sunday laws exist in all the States, with a single exception. The statutes of the States differ somewhat in details and strictness. Sunday is everywhere held as a *dieu non*. Public affairs are suspended; the legislatures do not sit; courts are not held, except that in some other police courts are open for six hours or two; legal processes are not served. In most of the States common labor and traffic are prohibited; amusements made or the services on Sunday are invalid; public amusements are restricted or forbidden. In many States partial exception is made for those who observe the seventh day of the week. The constitutionality of Sunday laws has been decided frequently by the highest State courts.

Sunday Letter: See DOMINICAL LETTER.

Sunday-schools: gatherings for religious instruction and worship, in which the learners are clustered in classes under separate teachers, all the classes being associated under a common head, and the form of instruction being introductory or colloquial. These characteristics include many schools which are held on Saturday, or which are known as First-day schools.

Modern Sunday-schools.—These had their origin in a movement begun by Robert Raikes, the proprietor of *The Gloucester Journal*, in Gloucester, England, in July, 1780. His purpose was to provide instruction in reading, and in the Church of England catechism, for the neglected children of a manufacturing district of that city. His first school was gathered on a Sunday in a private house under the charge of four women, who were employed at a shilling a day. Its forenoon session was from ten to twelve o'clock. In the afternoon, after a brief session, the children were conducted to the parish church for a part in worship, and were afterwards examined in the catechism. The Rev. Thomas Stothard, a parish clergyman, assisted Mr. Raikes in this work, and gave an extra shilling a day to the teachers.

Descriptions of this movement in *The Gloucester Journal* and other periodicals in 1788 called public attention to it, and it soon became widely popular. Voluntary teachers took the place of paid ones. The queen gave it her approval by sending for Mr. Raikes to tell her its story, and to congratulate him on what he was doing. Bishop Porteus was an early and earnest friend of the movement. John Wesley introduced its plan of work into his religious operations. A general Sunday-school society was organized with the aid of William Fox and James Hailey, having its center in London. The success of the movement was quickly

assured, although not without opposition from ecclesiastical authorities and timid reformers. A council of bishops was summoned by the Archbishop of Canterbury to consider the best means of checking the innovation; and the Presbyterians of Scotland and the Unitarianismists of New England took stand against it as tending to the secularization of the Sabbath. Within four years from the public announcement of his work by Mr. Raikes, however, the membership of such schools in the United Kingdom numbered over a quarter of a million, and the increase of their numbers has been constant.

Ancient Jewish Schools.—Although this was the beginning of the modern Sunday-school movement, its idea was of ancient origin, and had found expression in various forms all along the ages. Religious instruction, apart from that which was given in the family, seems to have been practiced in the days of Abraham (Gen. xiv. 13). Home instruction was not deemed sufficient for the children under the Mosaic law (Deut. xxxi. 12-13). The Levites were traveling Bible-teachers in the days of the kings of Judah (2 Chron. xvii. 9). The synagogue seems to have included in its exercises from its beginning, during the captivity, the study of the law by introductory methods. According to the Talmud and to Josephus, a system of religious schools in connection with the synagogues was organized in the century before Christ. This system included many of the features of the modern Sunday-school. The size of classes was limited to the capability of the teacher. Selected Bible lessons were arranged for a series of years. Attention was given to the fitness of instruction to the ability and needs of the pupils. Freedom in questions and answers was cultivated. Such schools were general in Palestine in the days of Jesus, and there is reason to suppose that he was a pupil in one of these in his Nazareth home.

Early Christian Schools.—The religious school was a prominent agency in the early Christian Church. "The apostolic Church," says Baron Hume, "made the school the connecting link between herself and the world." Catechizing engaged the best efforts of the best Christian teachers. A compulsory system of Bible schools for children in every city was in force in extensive fields as early as the fourth century, and charity schools in all country churches were ordered by a general council of the Church in A. D. 680. Such work was never wholly lost sight of even in the Dark Ages, although as the ecclesiastical spirit began to predominate over the evangelical less attention was given to it. In the Reformation of the sixteenth century the school idea gained new prominence. Paul Luther: "For the Church's sake Christian schools must be established and maintained. . . . God maintains the Church through the schools." And he acted on this idea, as did also Calvin, Zwingle, Beza, Knox, Cranmer, Ridley, Fisher, and others. Under Jesuit lead the Roman Catholic Church paid fresh attention to schools, and regained a measure of its lost ground through methods with children similar to those now in use in Sunday-schools generally. Two epochs combined to check the progress of what might be called "the Sunday-school idea" after its revival in the sixteenth century. The unintelligent memorizing of set answers, in catechisms intended as a mere guide in teaching, gradually took the place of religious teaching; and the polemical spirit among Protestants lifted argument into an undue prominence over Bible study. A marked religious decline was the result, and social and personal morals were at a very low point in the latter half of the eighteenth century, when the new movement in favor of Sunday-schools was begun by Robert Raikes.

Modern Beginnings before Raikes.—The plan of Raikes was only the new application of an old idea, but the circumstances of his beginning gave fresh importance to his work, and therefore its date marks a new era. Single schools much like his are claimed to have been started before that date, as follows: In Bath, England (by Rev. Joseph Allibon, in 1665-66); in Heshbury, Mass., in 1674; in Norwich, Conn., in 1676; in Plymouth, Mass., in 1699; in Newtown, Long Island (by Rev. Morgan Jones, in 1693); in England (by Bishop Prebington), in 1693; in Berks and Montgomery cos., Pa. (by the Schwankholders, in 1734); in Savannah, Ga. (by Rev. John Wesley, in 1737); in Ephrata, Pa. (by Jacob Hooker, in 1740); in Bethlehem, Conn. (by Rev. Joseph Bellamy, in 1740); in Philadelphia, Pa. (by Mrs. Greenough, in 1744); in Northern Scotland (by Rev. Mr. Morrison, in 1757); in Brechin, Scotland (by Rev. David Blane, in 1760); in Caterick, England (by Rev. Theophilus Lindsay, in 1763); in Columbia, Conn. (by Rev. Eleazer Wheelock, in

1763; in Bedale, England (by Miss Harrison), in 1765; in High Wycombe, England (by Miss Hannah Ball), in 1769; in Doagh, County Antrim, Ireland (by William Galt), in 1770; in Bright, County Down, Ireland (by Rev. Dr. Kennedy), in 1774; in Little Lever, near Bolton, England (by James Heys), in 1775; in Mansfield, England (by Rev. David Simpson), in 1778; also about the same time in Asbury, England (by Rev. Thomas Stock), and in Dursley, England (by William King).

Beginnings in the U. S.—For the credit of introducing the modern Sunday-school into the U. S. there are many claimants. It would seem that in several places Sunday-schools which were started within a few years after Raikes's beginning in Gloucester were continued for a time and then given up without leaving immediate successors. Thus a Sunday-school was organized under the direction of Bishop Asbury at the house of Thomas Crenshaw, in Hanover co., Va., in 1786; yet little is known of it save its beginning. A minute in favor of organizing Sunday-schools was adopted by the Methodist Conference in Charleston, S. C., in Feb., 1790; yet no record is found of Sunday-schools organized. In Dec., 1790, a meeting was called in Philadelphia to consider the importance of this work, and early in Jan., 1791, the First-day or Sunday-school Society was formed for the purpose of securing religious instruction to poor children on Sunday. This society is still active, yet its schools, like those of Robert Raikes, had paid teachers during the earlier years of its operation. In 1791 there was started a Sunday-school in Boston; in 1793 one in New York by Katy Ferguson, a Negro; in 1794 one in Paterson, N. J.; in 1797 one in Pawtucket, R. I., by Samuel Slater; in 1800 one in Pittsburg, Pa. In 1803 a Sunday-school was gathered by Mr. and Mrs. Divie Bethune in New York, and subsequently other schools were begun by them. Mrs. Bethune was a daughter of Mrs. Isabella Graham the philanthropist. Mr. Bethune had seen something of Raikes's work in England, and the New York school was in imitation of that. In the same year with this beginning in New York a Sunday-school was begun in Portsmouth, N. H., and the year following one in Baltimore, Md. In 1809 a systematic Sunday-school movement was organized in Pittsburg, Pa. The Rev. Robert May, from London, gave a new start to Sunday-schools in Philadelphia in 1811, which proved a beginning of permanent progress. A local union for Sunday-school work was organized in New York in 1816, another in Boston the same year, and another in Philadelphia in 1817. These societies became the nucleus of the American Sunday-school Union, a national society organized in 1824.

Progress and Influence.—The Sunday-school movement led to a new interest in popular education, and to new measures for the Christian evangelization of the home field and the foreign. J. R. Green, the historian, says: "The Sunday-schools established by Mr. Raikes . . . were the beginning of popular education." The system of penny postage, and the organization of the British and Foreign Bible Society, and of other benevolent societies, were an outgrowth of interest in this movement. Adam Smith said at the time: "No plan has promised to effect a change of manners, with equal ease and simplicity, since the days of the apostles." A century later John Bright, looking back on the record, said: "There is no field of labor, no field of Christian benevolence, which has yielded a greater harvest to our national interests and national character than the great institution of Sunday-schools."

In the U. S. the influence of the Sunday-school has been even more important than in Great Britain. When the Sunday-school was introduced as a practical power into the U. S., unbelief and error were already largely in the ascendant, and a flood of godless immigration was making the matter worse year by year. The new agency was by various changes adapted to the peculiar needs of the republic, and it became a means of instructing and influencing children and youth in the field of organized churches and of pioneer religious work in new communities.

Present Status.—The Sunday-school is a recognized department of the Church in the U. S. for the religious instruction of the young, and for systematic Bible study by young and old. It is also employed as a pioneer agency of evangelism in newer portions of both the older and the newer communities, as in the outlying districts of cities and villages, and on the borders of an advancing and extending population, beyond the limits of existing church organizations. Both as a denominational and as an undenominational

agency it is of marked and growing prominence. Protestants and Roman Catholics alike recognize its importance, and it is in favor among the Jews as among Christians. Its management varies according to the ecclesiastical systems of which it has become a part, but its main features are alike throughout.

Buildings for the use of Sunday-schools are often arranged so that numerous rooms can be used separately, and yet all opened together into the sight of the superintendent's desk at a moment's notice. Sunday-school hymns and music are an important aid to social worship. An extensive literature, in the form of books and periodicals, has been created by and for the Sunday-school. Improved methods of teaching have been promoted by Sunday-school normal classes and teachers' institutes. Conventions and assemblies have extended the influence and uplifted the standard of Sunday-school instruction.

International Lessons.—In 1873 a plan of uniform Bible lessons was formally inaugurated, on the recommendation of a national convention of Sunday-school workers, and that plan was approved in Canada and England, and came to be known as the international system. Gradually this system overbore opposition, and was employed more and more generally in North America and throughout the world, until now from 6,000,000 to 8,000,000 are engaged each week in the study of the Bible according to its outline. This centering of interest on particular portions of the Bible has justified the issue of many special works as aids to intelligent study, and of the employment of the ablest scholarship and talent for critical and popular expositions. As a result, there is more of biblical study and of interest in biblical research than at any previous stage in the world's history. Criticisms of this international system and attempts at a better one have been incessant, but it has made progress steadily in public favor. A scheme of Bible lessons widely used in the U. S., and considered by many as an improvement upon the international lessons, is known as the Blakeslee or inductive system; and other schemes have their enthusiastic advocates.

The influence of the Sunday-school has been manifestly for good over the individual, the family, and the community; and schools, colleges, and churches have felt that influence, as widely and as steadily as the Sunday-school has made progress.

The following statistics of Sunday-schools in all nations were compiled for the second world's Sunday-school convention, at St. Louis, Mo., Sept. 4 and 5, 1893:

COUNTRY.	Sunday-schools.	Teachers.	Scholars.

H. CLAY TRUMBULL.

Sunderland: town in the county of Durham, England, at the mouth of the Wear; 12 miles S. E. of Newcastle-upon-Tyne and 13 miles N. E. of Durham (see map of England, vol. 4-11). The borough includes Sunderland proper and other townships on the south side of the Wear, and Monkwearmouth on the north side, the river being crossed by two iron bridges. Sunderland is a well-built modern town with broad streets. Among the principal buildings are the Renaissance town-hall, completed in 1890, and the museum, art gallery, etc. (1919). The harbor is formed by two piers, 1,850 and 650 feet long respectively. Two new piers 2,570 and 2,700 feet long, including a harbor of 125 acres, are in process of construction (1895). Four docks, covering a total space of 48 acres, are capable of receiving the largest vessels. The shipments of coal and coke average upward of 4,000,000 tons; in 1892 1,369,546 tons were exported. Glass, earthenware, iron, lime, cement, and chemicals are also exported. The principal imports are iron ores, timber, chalk, and agricultural produce. The total tonnage entered and cleared in 1899, exclusive of that coastwise, was 1,979,793. Ship-building is largely carried on; in 1892 67 steamers, with a total tonnage of 174,940, were launched. Other industries are iron-works, bottle-works, chemical works, ropewalks, paper-mills, and breweries. In Monkwearmouth is one of the deepest collieries in the world (281 fathoms). Pop. of the municipal borough (1894) 136,101; of the parliamentary borough, returning two members (1891), 142,097. R. A. B.

Sunderland, JAMES THOMAS, A. B., B. D., A. M.; clergyman and author; b. at Howarth, Yorkshire, England, Feb. 11, 1842; educated at Madison University, Hamilton, N. Y., University of Chicago, and Union Baptist Theological Seminary, Chicago; held pastorates in Milwaukee, Wis., North-Rail, Mass., Chicago, Ill., and Ann Arbor, Mich.; published *A Rational Faith* (1878); *What is the Bible?* (1878); *The Liberal Christian Ministry* (1889); *Home Travel in Bible Lands* (1891); *The Bible, its Origin, Growth, and Character and Place among the Sacred Books of the World* (1893); and various minor works; established and became the editor of *The Unitarian*, a monthly, in 1896.

Sunderland, ROBERT SPOONER, Second Earl of; politician; b. in 1640; lived on the Continent during the time of the Commonwealth; returned to England at the restoration of Charles II.; was sent on embassies to Madrid, Paris, and Cologne, 1671-73, and became Secretary of State in 1679. He at first opposed and then supported the bill for the exclusion of the Duke of York, afterward James II., and was removed from office by Charles in 1691, but was reinstated in 1692, and exercised a controlling influence in the Government during the remainder of the reign. He was continued in office by James II. and is said to have become a Roman Catholic, but, being opposed to some of the radical measures of the court, was dismissed in 1688, and took refuge in Holland. He gained the favor of William, and in 1697 was made lord chamberlain, but retired from public life in 1697 with the reputation of having been the basest public man of his age. D. at his seat, Althorpe, Sept. 28, 1762.—CHARLES SPOONER, his son, the third earl, b. in 1674, professed liberal principles, and was returned to Parliament for Tiverton in 1695. His first wife, a daughter of the Duke of Newcastle, having died, he married in 1699 a daughter of the Duke of Marlborough, thereby strengthening his alliance with the dominant Whig party. He succeeded to the earldom in 1702; distinguished himself on a mission to Vienna, and from 1701 to 1710 was Secretary of State; was dismissed in 1710, declining a large pension offered him by the queen. Upon the accession of George I. in 1714, he was made Lord-Lieutenant of Ireland, in 1715 Lord Privy Seal, and in 1718 Prime Minister. He was apparently deeply involved in the South Sea

Bubble, and though in an investigation by the House of Commons he was acquitted of personal corruption by a vote of 221 to 173, he was driven from office in 1721. D. Apr. 19, 1722. P. M. COLBY.

Sunder: See DUMBERA AND INSECTIVOROUS PLANTS.

Sun-dial: See DIAL.

Sun-dog: See HALO.

Sunfish: a name given to different aquatic animals on account of their brilliant colors, shape, or habit of basking in the sun. (1) In the U. S. and Canada it is most frequently applied to species of freshwater fishes belonging to the family *Centropomidae*, and chiefly to the genus *Lepomis*. These are readily recognized by the extension of the opercula backward into narrow or less enlarged or elongated membranous, highly colored, sail-like lobes, and the radial formula—viz., dorsal fin with ten spines and ten or eleven rays, and anal fin with three spines and nine or ten rays; the colors are always quite brilliant. The species are quite numerous. The best known in the Northern States are the (1) *Lepomis gibbosus vulgaris*; (2) *L. auratus*; and (3) *Lepomis pallidus*. The *L. gibbosus* is the common sunfish of New England and the Middle States, and is at once recognizable by the ear-flaps being black, tipped with scarlet, and by the orange spots of the sides. The *L. auratus* is equally readily distinguishable by the very long black not distinct edged ear-flaps. The *L. pallidus* has sparsely black ear-flaps. The first is the smallest, and the last two the largest of the species mentioned. Wherever found, they are generally among the most common fishes. They are quite carnivorous and bold, and take a look baited with the common earthworm with avidity. Many of the species build curious nests. (2) On the seacoast, to some extent, but more especially in Great Britain, the name is given to species of *Orthopristis* or *Mola*, fishes of an almost circular outline, with high anal and dorsal fins and an aborted tail. (3) In some parts of England the name is also applied to the basking shark (*Cetorhinus* or *Detorhinus maximus*). (4) It is also frequently applied by sailors to the species of floating water-leaves or jellyfishes. Revised by P. A. LORAN.

Sunflower: the *Helianthus annuus*, a coarse and tall annual plant of the family *Compositae*. It is often seen in gardens and is well known for its large and showy compound flowers. It is a native of the Great Plains of North America, where it grows in great abundance. In Europe the plant is raised for its seeds, which afford a good drying oil, nearly equal to that of linseed. The leaves are fed to cattle, the seeds to poultry, and the flowers yield good honey. The planting of sunflowers is reputed to be a preventive of miasmatic fevers. The pith is sometimes used instead of the true moss. In tropical America the sunflower often attains a height of 20 feet and produces a flower of from 1 to 2 feet in diameter. In Southern Europe it is cultivated as a field-crop on account of its seed. See COMPOSITEAE for illustration. Revised by CHARLES E. HANSEN.

Sunflower Family: another name for the *Compositae* (q. v.).

Sungaria, or **Zungaria** (sometimes *Jungoria*): the country of the Sungars or Kalmauks; a geographical expression of no scientific value, loosely used to indicate the region that was once the center of the kingdom established early in the eighteenth century by the Sungars or Manchu of the left wing. It is a plateau of moderate elevation, bounded on the S. by an eastern extension of the Tianshan or Celestial Mountains; has the Russian provinces of Semirechinsk and Semipalatinsk on the W. and N. W., and is separated on the N. E. from Kokoda in Mongolia by the Great Altai Mountains. It is intersected by minor chains which divide the region into several basins with a number of considerable lakes. It includes the valley of the Ili, and with Chinese Turkestan to the S. it forms what is called *Sinkiang* (or *shing*), the "New Frontier" province of the Chinese empire. The population of Sungaria has been estimated at 2,000,000. Capital, Kulja. R. L.

Sunn Hemp: the fiber of the *Crotalaria juncea*, a leguminous herb of Bengal, extensively cultivated in India both for its fiber and as a forage-plant for cows. The sunn hemp is exported extensively. It is inferior to true hemp, but better than jute, and is used for cables and manes.

Sun'nites: all methods Musulmans. They are so called as adherents of the *Sunnah* or tradition, a collection of prophetic laws, which embrace (1) the remarks and com-

sels uttered by the Prophet; (2) his deeds and practices; and (3) his silence, it being considered that what the Prophet abstained from doing or saying fully indicates his opinion and hence the duty of his followers. The Sunnites are divided as to ritual into four classes, the Hanefites, Malekites, Schafites, and Hannbelites. See MOHAMMEDANISM. E. A. G.

Sunstroke, Insolation, or Coup de Soleil: See THERMIC FEVER.

Sun-worship: commonly regarded as one of the characteristic features of the religion of ancient Persia. The Peruvians of old who worshiped every aspect of nature, paid the chief honors to the sun. The Egyptians, the Greeks, the Italians of antiquity, and the Celtic and Teutonic races, the East Indians, and some African pagans, were, as some heathen races still are, sun-worshippers. In fact, sun-worship is one of the most widely diffused forms of nature-worship, the genial and fructifying warmth and brightness, the mysterious nature, and the constant course of the great luminary appealing powerfully to the religious feelings of the ruder peoples. See the article WORSHIP.

Revised by A. V. WILLIAMS JACKSON.

Supererogation, Works of [*supererogation* is from Late Lat. *supererogatio*, deriv. of *supererogare*, pay out in addition; Lat. *super*, over, above + *erogare*, pay out, expend; *e*, out + *roga're*, ask]: in the Roman Catholic Church, good works performed by a Christian over and above his simple duty. These works, it is alleged, constitute a fund of merit which is applied to the relief of souls in purgatory. The definition is based on a distinction between what is commanded and what is only counseled—a distinction which is known only to Roman Catholic dogmatics.

Superior: city: port of entry: capital of Douglas co., Wis.: at the head of Lake Superior, on St. Louis, Superior, and Allouez Bays, and the Gt. North. N. Pac., Chi., St. P., Minn. and Om., St. P. and Duluth, Dul. and Winnipeg, and the Dul., S. Shore and Atl. railways; opposite Duluth, Minn. (for location, see map of Wisconsin, ref. 2-B). It has three perfect landlocked harbors, all connected, with total length of 13 miles and width of from 1 to 3 miles. The city is platted at right angles to the water front, with streets 80 feet wide, avenues 100 feet, and alleys 20 feet. The climate is crisp, dry, and healthful, with average temperature for twenty years 40°; average velocity of wind, 7 miles per hour; average number of fair and clear days per annum, 260. The water-supply is drawn from Lake Superior, and the sewerage system, planned when the city was laid out, is sufficient for a city of 1,500,000 people. There are 31 miles of paved streets, 89 miles of graded streets, 47 miles of sewers, 87 miles of sidewalks, 43 miles of water-mains, 15 miles of gas-mains, and 15 miles of double-track electric railway.

Churches and Schools.—Superior has 36 church organizations and 35 church edifices. There are 12 public schools, with 96 teachers and 5,160 pupils, 4 parochial schools, a Finnish university, and a business college. The public-school buildings cost \$456,000.

Finances and Banking.—The assessed valuation in 1894 was \$19,680,000; bonded debt, general, \$363,598; special improvements, \$942,667; school district bonds, \$235,000. In 1895 there were 3 national banks with combined capital of \$635,000, 8 State banks with capital of \$600,000, 5 loan and investment companies, and 5 building and loan associations, local and serial, with 447 shareholders and 7,159 shares in force.

Business Interests.—The manufactures are chiefly flour, lumber, lath, shingles, iron, wagons, chairs, barrels, bags, coke, and woolen goods. There are 8 flour-mills with a combined capacity of 23,000 barrels per day; 9 elevators with a storage capacity of 15,000,000 bush.; 8 coal-docks with a capacity of 6,000,000 tons, one of which is the largest in the world, with capacity of 4,000,000 tons, and one of solid steel in which all coal-handling is done in large steel tunnels beneath the ground; a bank of coking-ovens; an iron-ore dock; shipyards for the construction of whaleback steamers; 4 sawmills; the largest dry dock on the Great Lakes; and many other industrial plants. The receipts by water are coal, oil, salt, cement, sugar, iron, and general merchandise; shipments, wheat, flour, lumber, copper, and wool. The port collector's official report for 1894 showed, arrivals and clearances, 2,001; tonnage, 2,830,000; coal receipts, 1,142,614 tons; wheat shipped, 10,739,000 bush.; flour shipped, 3,077,000 barrels; lumber shipped, 24,600,000 feet; copper, iron ore, etc., shipped, 560,000 tons; and wheat in store on Jan. 1, 1895, 7,110,000 bush.

Shipping Facilities.—Besides those furnished by the railways, the city has exceptional facilities for receiving and shipping freight by water. The water front is divided into harbor districts, so that the city may make improvements in any one of them when needed and charge the cost to the property in the district. There are 10 miles of substantial wharfage, and the water front may be slipped so as to furnish 138 miles of wharfage. The U. S. Government has expended \$650,000, and private parties about \$600,000 in harbor improvements; and the city \$3,200,000 and private corporations and parties \$2,225,000 on docks.

History.—Superior was a station of the Hudson Bay Company, over 200 years ago; trading-post for Daniel Greyschlon du Lhut (Duluth) in 1680; and headquarters for Radisson and Grosseilliers in 1661. In 1853, when it was supposed the U. S. Congress would charter and subsidize the Northern Pac. Railroad from Lake Superior to the Pacific Ocean, and after the great land grant had been made by Congress to the State of Michigan to aid in constructing the first canal and locks around St. Mary's Falls, distinguished men preempted the land where Superior now stands for a town-site. The canal was completed and a land office and lighthouse established at Superior in 1855, and the town boomed. The Northern Pacific charter failed and the panic of 1857 paralyzed the city. In 1881 the Northern Pacific Railroad, for a gift of about half the town-site, built a branch to the water front and erected a dock. In 1883 Gen. John H. Hammond organized a company which acquired land W. of the original town-site, on St. Louis and Superior Bays, and in 1885 platted a new city. In laying out the town a right of way was provided for terminal tracks to reach every railway coming to the head of the lake, and connecting them with every dock and slip on the entire 90 miles of water front. More than 1,000 acres of land near the bay and on one side of the town, separated from all residence and business streets, was reserved exclusively for railway, switching, and storage yards. Thus every dock, mill, and wholesale house has equal facilities for receiving and shipping freight over all the railways at the head of the lake. The city comprises the parts locally known as East Superior, West Superior, South Superior, and Old Superior. Pop. (1880) Douglas County, 655; (1890) city, 11,983; (1894) estimate on school census, 35,000.

FRANK A. FLOWER, PROPRIETOR OF "LEADER."

Superior, Lake: the largest of the Laurentian chain of lakes. It is also the largest fresh-water lake in the world, and the largest inland water-body except the Caspian Sea. Its area, as determined from the charts of the U. S. lake survey, is 30,829 sq. miles; another computation from the same data gave 31,200 sq. miles. The only possible rival to Lake Superior in size is Lake Victoria Nyanza, which is estimated to have an area of 27,000 sq. miles. The mean elevation of the surface of Lake Superior is 602 feet above the sea, and 20 feet above Lake Huron, into which it discharges through St. Mary's river. Its greatest measured depth is 1,008 feet; the bottom of the basin is therefore over 400 feet below sea-level. Its hydrographic basin, including the lake surface, has an area of about 85,000 sq. miles. The mean discharge through St. Mary's river is estimated at 16,000 cubic feet per second. In the deeper portions of the lake the temperature varies but little from 39° F., the temperature of water at its maximum density. Analyses have shown that the water at all depths is fresh.

The boundary between Canada and the U. S. passes through the lake, about one-third of the area of the latter belonging to the Dominion. The north shore is formed of crystalline rocks, and in places is bold and picturesque. The southern shore is mostly low and covered to a great extent with blown sand, glacial deposits, and fine, evenly laminated, pinkish clays, which were deposited from the lake during a former high-water stage, when it extended for many miles S. of its present boundaries. The rocks beneath those superficial deposits belong mainly to the Algonkian period, which includes the copper and iron bearing series, and to the Cambrian period, which includes the red sandstone, largely used for building in Marquette and other cities. The Pictured Rocks, about 100 miles W. of the outlet of the lake, are cliffs of sandstone, formed by the edges of nearly horizontal strata, and together with other bold features about the lake are remnants of an old topography which was fashioned by stream erosion and weathering previous to the Glacial period.

The land bordering Lake Superior is not well adapted for

agriculture, but rich deposits of copper and iron, and abundant forests of pine, together with fisheries and the facilities for transportation which the lake affords, have led to rapid developments. See also ST. LAWRENCE RIVER AND GULF.

ISRAEL C. RUSSELL.

Supernatural: See MIRACLES.

Suphis [Egypt, *Khufu*, the *Cheops* of Herodotus and the *Chummi* of Diodorus]: name given by Manetho to the second king of the fourth Egyptian dynasty. Besides prosecuting the wars inaugurated by his predecessor, Snofru (see *SORIS*), against the tribes of Sinai, he was engaged in gigantic building operations in Egypt. The largest pyramid at Gizeh (see *PYRAMIDS*) was erected as his tomb, and three smaller pyramids near by were erected for relatives. The founding of the temple of Hathor at Denderah is also ascribed to him. According to Manetho he reigned sixty-three years, but the Turin papyrus reduces the time to twenty-three or twenty-four years.

CHARLES R. GILLET.

Suppé, soop'pá', FRANZ, von: opera-composer, whose baptismal name was Francesco Ezechiele Ermengildo Cavaliere Suppé Demelli: b. Apr. 18, 1820, on board ship near Spalato. He very early manifested musical talent, and at fifteen composed a mass which was sung at the Franciscan church at Zara. After study with the best masters he became conductor at the Josephstadt theater, Vienna, succeeded by other similar engagements. His first operatic work was *Sommernachts Traum*, founded on Shakspeare, in 1844. Then came a long list of operettas, many of which were very popular. In the U. S. he is best known by his *Faluitza*, *Boccaccio*, and his overture *Poet and Peasant*. D. in Vienna, May 21, 1895.

D. E. HERVEY.

Supper, Lord's: See EUCARIST.

Suppressio Veri: See FRAUD.

Suppuration [from Lat. *suppuratio*, deriv. of *suppurare*, suppurate, form matter: *sub*, under, from under, (in compos.) up + *pus*, *puris*, matter, pus]: a form of inflammation which goes on to the development of *pus* or matter. This is seen in abscesses, inflammations of the mucous membranes, and in granulating wounds. The product is a creamy yellow liquid composed of a fluid part, the *liquor purus*, and cellular elements, the *pus corpuscles*. The causes of suppuration have occasioned much study. Formerly a variety of traumatic, chemical, or other local injuries, together with certain general bodily conditions, were regarded as causes; but after the development of bacteriology attention was directed to micro-organisms as the active agents. Certain bacteria are now recognized as pus-producing or *pyogenic*; but it is also admitted that suppuration may occur spontaneously or experimentally without the presence of bacteria. Injections of calomel, turpentine, and certain other substances, for example, are capable of exciting suppuration. In studying the process microscopically it is found that, as in other forms of inflammation, the white blood-corpuscles of the blood leave the vessels and accumulate in the tissues;

Pus corpuscles, as seen in healthy pus. The same, after the addition of acetic acid.

at the same time a quantity of the fluid part of the blood exudes. Eventually the cellular exudate softens by degeneration, and yellowish pus results. At the same time the surrounding tissues produce a wall of young cells around the periphery of the suppurating focus, and thus an abscess with a retaining wall is formed. The older theory of the origin of pus-cells, viz., that they are altered tissue-cells, is thus seen to be abandoned. It is likely, of course, that some of the cells of a tissue are loosened and mingle with the pus, but the true pus-corpuscle itself is a white blood-corpuscle which has emerged from the blood-vessels and subsequently undergone more or less degeneration. When treated with acetic acid the protoplasm of the cells clears, and reveals a multiple nucleus, as shown in the accompanying illustration. The multinuclear character of the pus-cells is explained by the discovery that only these forms of white corpuscles have the property of readily escaping from the blood-vessels.

Pus formed on the free surfaces, as in bronchitis, nasal catarrh, in granulating wounds, and the like, comes from the underlying blood-vessels, and filters through the superficial lining cells. Spreading suppuration is found in erysipelas, and certain other conditions in the submucous or

subcutaneous tissues. The symptoms indicative of suppuration are those of inflammation—heat, redness, pain, and swelling; but the pain has often a peculiar throbbing character, and the swelling is found to be fluctuating or elastic. In addition, general fever of irregular type, sweats, or chills may be noted; and general infection of the blood (pyæmia and septicæmia) may occur.

The treatment of suppuration consists in abortive measures, and, these failing, in measures to promote "pointing," and in the evacuation of the abscess. Applications of cold are most useful for the first purpose; for the second heat, and especially poultices, is of value. After the development of fluctuation incision is called for.

W. PEPPER.

Supremacy, Act of: See ACT.

Sur, or **Noor** (anc. *Tyros*): town: in the province of Syria, Asiatic Turkey; on an island in the Mediterranean, which Alexander the Great, when besieging Tyre, connected with the mainland by a broad dam. Sur has suffered very much from earthquakes, and its harbor has become so silted up as to be accessible for small vessels only. Pop. about 5,000.

Surabaya, soo-rû-bi-ân: town on the north coast of Java; capital of the Dutch province of Surabaya; opposite Madura, at the mouth of the Kediri (see map of East Indies, ref. 8-E). It has a good harbor, is strongly fortified, and contains barracks, magazines, hospitals, and other military establishments. It is a station on the railway from Surakarta to Probolinggo, communicates regularly with Samarang, Batavia, and other places by steamboats, and carries on an important trade, exporting annually rice, coffee, cotton, sugar, tobacco, and coconuts. Its ship-building is also extensive. Pop. (1890) 107,878, of whom 6,000 (1892) are Europeans, the rest Javanese, Malays, and Chinese.

Revised by M. W. HARRINGTON.

Surakarta: town of Java; capital of the Dutch residency of Surakarta; on the left bank of the Solo; connected with Samarang and Surabaya by railway (see map of East Indies, ref. 8-E). It contains a magnificent palace of the native emperor, who lives here as a pensioned rather than as a tributary prince; the Dutch fortress is opposite the emperor's palace. The trade is very large, especially in pepper, vanilla, and cacao. Pop. (1890) 91,368.

Surat: town: in the presidency of Bombay, British India; on the Taptee, in lat. 21° 12' N., lon. 72° 47' E. (see map of S. India, ref. 2-C). It is 6 miles in circumference, and surrounded by walls surmounted by towers. It is said to have had 800,000 inhabitants at the end of the eighteenth century, but its manufactures died out, its trade is lost, and many of the Dutch, French, and Portuguese establishments are deserted. The place is most important from a military point of view. Pop. (1891) 109,229.

M. W. H.

Surd: See SOXANT.

Surety: See GUARANTY and SURETYSHIP.

Suretyship [viâ O. Fr. from Lat. *securitas*, safety, security, (Late Lat.) security for a debt]: a term covering all cases of secondary liability of one person for the debt, default, or miscarriage of another, who is the primary obligor, whether the relationship results from express agreement or from implication. GUARANTY (*q. v.*) and indorsement (see BILL OF EXCHANGE and NEGOTIABLE INSTRUMENTS) are embraced by this definition. The word is used frequently in a specific sense to designate the relationship existing where the primary and secondary obligations are assumed in a single contract, as where one person signs a promissory note as maker and another adds his signature as surety. The distinction between suretyship in this sense and guaranty is stated clearly in a leading case as follows: "A contract of suretyship is a direct liability to the creditor for the act to be performed by the debtor, and a guaranty is a liability only for his ability to perform this act. From the nature of the former the undertaking is immediate and direct that the act shall be done, which if not done makes the surety responsible at once."

The creditor is under no legal obligation, as a rule, to disclose all the facts affecting the surety's risk. If, however, he makes any misrepresentation as to the subject-matter of the surety's undertaking, the latter will not be bound. The general principles governing the formation of this contract have been thus stated: "The surety is entitled to know the real nature of the transaction he guarantees and of the liability he is undertaking, and generally and naturally he looks to the creditor for information on this point, although he usually is acting at the debtor's request and as his friend,

and so relies on him for collateral information as to general credit and the like. In that case the creditor's description of the transaction amounts to or is at least evidence of a representation that there is nothing further that might not naturally be expected to take place between the parties to a transaction such as described." Accordingly, it has been held that a bank can not enforce against the sureties a bond for the faithful and honest conduct of a teller who was known to the bank officers to have been dishonest unless such dishonesty was disclosed to the sureties before their execution of the bond. The failure to communicate such knowledge is declared to be fraudulent toward the sureties. Express contracts of suretyship are to be construed so as to give effect to the intention of the parties. The language is to be read in the light of the circumstances surrounding the execution of the instrument, and full effect is to be given to its meaning as thus ascertained. The surety's responsibility is not to be extended or enlarged by implication or construction, but is to be treated as *strictissimi juris*. It is also well established that any change in the contract made by the creditor and primary debtor without the surety's consent discharges the latter. Nor will the courts inquire whether the change operates to increase or diminish the surety's burden. He has a right to stand upon his own terms. An extension of the term of credit, however slight, pursuant to a binding agreement between the principals, must be assented to by the surety or he will be released.

Upon discharging his principal's obligation the surety is entitled to SUBROGATION (*q. v.*), to all the creditor's rights and securities. If there are two or more sureties either is entitled to CONTRIBUTION (*q. v.*) from the others.

FRANCIS M. BURDICK.

Surface: in mathematics, the locus of a point in space whose co-ordinates are connected by a single relation. It may also be generated by the movement of a straight or curved line. A surface forms the superficial configuration or boundary of a solid. It is said to be of the *n*th degree, when it is intersected by an arbitrary line in *n* points, real or imaginary. The surface of the first degree is a plane, and the surface of the second degree includes several varieties, treated under CONE, CYLINDER, HYPERBOLOID, PARABOLOID, SPHERE, and SPHEROID (*qq. v.*).

Surf-bird: a small wading bird (*Aphriza virgata*) of the American Pacific coasts, about 10 inches long, named from its habit of allowing the surf occasionally to dash over it as it seeks its prey on the rocky shores. Its flight is short and irregular. It is related to the oyster-catchers and the turnstones.

F. A. L.

Surf-duck: a seacoast duck of America, the *Oidemia perspicillata*, known to gunners as the skunk-head coot. It belongs to the group called scoters in Great Britain and coots in the U. S. It is quite black, except a little patch of white on the head and another on the nape.

F. A. L.

Surgeon, or Surgeon-fish: a fish of the family ACANTHURIDÆ (*q. v.*).

Surgery [M. Eng. *surgerie*, from O. Fr. *chirurgie* > Fr. *chirurgie* < Lat. *chirurgi'a* = Gr. *χειρουργία*, handicraft, skill, surgery, deriv. of *χειρουργός*, working by hand, handicraftsman, skilled workman, surgeon; *χείρ*, hand + *εργον*, work]: that branch of medical science which has for its object the treatment by manual operations of all lesions or malformations of the human body.

It is probable that in antiquity of origin surgery must take precedence of medicine, since attempts to assuage the pain or to remove the inconveniences of wounds or injuries resulting from external violence would be likely to be made before internal diseases were in any degree understood or supposed to be within the control of human means. Baron Percy has remarked that, while the internal diseases of mankind were still ascribed to the anger of the gods, and the smoke of expiatory sacrifices ascended from altars, surgeons had already become renowned by bold and salutary operations. He is inclined to attribute the origin of this art to the first occasion when some one, pierced by a foreign body, invoked the aid of a skillful comrade for its removal, remarking that in ancient times it was sufficient to extract adroitly darts or arrows, and to place on the wounded part some soothing balm, in order to be reckoned a benefactor of humanity entitled to divine honors (Homer, *Iliad*, lib. xi.). Students of Sanskrit literature, and those who have sought to decipher the inscriptions of Egyptian and Assyrian ruins, find some grounds for the belief that surgery was more

advanced among those ancient peoples than is commonly supposed, pictures and *bass-reliefs* having been found displaying surgical instruments and operations not unlike many in use in modern times. It is certain, at least, that the custom of embalming the dead, which implies some anatomical and surgical knowledge, was prevalent in very early times, and that among the Jews the operation of circumcision was practiced by divine command through many ages.

Greek.—The first definite traditions regarding surgery, and the first collected body of doctrine, came from the Greeks, who were, however, the pupils of the Asiatics and Egyptians, and Dujardin, in his erudite *History of Surgery*, has carefully traced the channels through which information was transmitted to a more gifted and brilliant nation. He would accept Plutarch's account, that Agenor, a Phœnician king, practiced surgery with distinction, dressing the wounded arm of a son of Priam, and devising the scarf or sling now so indispensable in many injuries of the upper extremities. Chiron, the Thessalian centaur, is more generally accredited the father of surgery in the fabulous ages of Grecian history. His reputation is eclipsed by that of Æsculapius, a son of Apollo, by some reckoned the pupil of Chiron, by others his contemporary and superior, believed to have been deified fifty years before the Trojan war, although skeptics have called his very existence in question. Jason, Theseus, and Hercules practiced surgery, and Epione, the wife of Æsculapius, as well as Medea, proved that women thus early not only shared with men the perils of war, but aided in repairing its ravages. A Thracian king, Orpheus, had such knowledge of the virtue of plants that he cured a woman bitten by a snake, whence arose the fable that he had rescued her from hell. The Greeks, prodigal in apotheosis, made many demigods partly because of their achievements in the healing art. Two sons of Æsculapius are named among the heroes of the *Iliad*. Menelaus, wounded by an arrow from Pandarus, and Philoctetes, struck by a poisoned javelin, are cured by the skillful Machaon; and Pausanias records that the Messenians, over whom he reigned, raised a temple to his honor. Podalirius, his brother, though much praised for his surgical skill in the Trojan war, has no important cures circumstantially ascribed to him, except that of the daughter of Damœtus, King of Caria, whom he bled from both arms when she was stunned by a fall, and, on her survival, married her, receiving the province of the Chersonese as a dowry. Hence the origin of phlebotomy is attributed to this surgeon. The surgical attainments of these sons of Æsculapius seem not to have extended further than the extraction of darts, the suppression of hæmorrhage by pressure or styptics, and the application of lenitive salves. Homer says that when the warriors at the Trojan siege sustained fractures of the bones, recourse was had, as when pestilence arose, to invocations to the gods.

For six centuries after the Trojan war there is little information of any advances in surgery. In common with other branches of knowledge, it was passing through that stage in which the intervention of supernatural powers is recognized rather than the scope of human possibilities. It was thus with the Asclepiadæ, or reputed descendants of Æsculapius, in the course of whose long monopoly, however, schools for the instruction in such surgical information as the professors possessed or were willing to impart were established about the temples, and those at Rhodes, Cnidos, and Cos became distinguished. Real achievements in surgery appear to have been known during this period, such as cutting for the stone and operating for cataract, although these advances were discredited by the priests, as suitable only for specialists of the baser sort.

Hippocratic Surgery.—It was not until Pythagoras brought the light of philosophy to bear upon the practice of the healing art that the way was paved toward raising its dignity in the direction of positive knowledge. The school that he founded at Crotona not only produced surgeons of distinction (among others, Damocedes, who, made captive by the Persians, treated Darius for a dislocated ankle and his Queen Atossa for a cancer of the breast), but also inspired the schools of Cnidos and Cos with the philosophic spirit, so that, a century later, there appeared in the latter that splendid genius Hippocrates. Born in the 80th Olympiad, about 460 years before the Christian era, this great man did much to free medicine from the absurdities with which superstition and ignorance had surrounded it, and through a long life gave a noble example of persevering industry, of philosophical research, and of lofty moral

wealth. His attention was more turned to medicine than to surgery, yet in the latter branch his practice was bold and fearless. He commended some operations that have only of late years been acknowledged to be legitimate surgical measures, such as tapping the chest for empyema, nephostomy for calculus lodged in the kidney, and trephining the skull for persistent headache. He was familiar with cauterization and venesection and cupping; with operations on the canals, nasal polyps, and ganglia; with the treatment of piths and disabs by ligatures; with tapping in dropsies, advising even paracentesis in hydrocephalus; with all the external procedures known in his day except the operations for lithotomy and cataract, which seem to have been confined to specialists. He gave rules for the most part rarely and cruel, for the reduction and treatment of dislocations and fractures, and anticipated a multitude of the practices that have been vaunted by the moderns. For many generations after Hippocrates surgery made little progress. The religious prejudices that forbade the dissection of the human body precluded the acquirement of any definite knowledge of anatomy, and there was a barren interval of several centuries. Of the more immediate successors of Hippocrates, Diocles of Carystus was one of the most prominent in surgery. He devised sundry bandages, especially for wounds of the head, and improved the *seton*, an instrument for extracting arrow-heads and darts, invented during the Peloponnesian war. Praxagoras of Cos is reported to have been a very bold surgeon, incising the fauces freely in cases of cyanosis, and laying open the abdomen for the removal of intestinal obstructions.

Alexandrian Period.—The labors of Aristotle had some influence in promoting the healing art; but there was no advance of any practical importance until, on the dismemberment of the great empire of Macedonia, the chief center of learning was transferred to Alexandria, and the Egyptian school took its rise (c. 300). Herophilus of Chalcedon and Erasistratus were the more conspicuous leaders of the Egyptian school. The former was a pupil of Praxagoras. He was the first to direct attention to the radial pulse as an index of the varying conditions of health and disease. According to Galen, he held as an anatomist among the ancients the same place as Vesalius among the moderns. That he dissected human bodies is expressly asserted by Galen. Dr. Marx is satisfied that he discriminated nerves of motion from those of sensation; that he described the occipital depression now known as the torcular Herophili as the point at which the sinuses of the dura mater converge; distinguished the cerebrum from the cerebellum; and named the *calamus scriptorius* of the medulla oblongata, and the *duodenum*, and also carefully dissected the tunics of the eye and originated the term *reflex*; and came near anticipating Aescli in the discovery of the bacteria, recognizing their relation with the mesenteric glands. Yet he fell into palpable mistakes, confounding the tendons and ligaments with nerves, and possibly the trachea with the *corda*.

Erasistratus, a native of Chios, who had studied philosophy under Theophrastus, is also greatly distinguished as an anatomist, but his erroneous interpretation of the function of the arteries, overthrown by Galen, retarded the discovery of the circulation, reserved for the illustrious Harvey. Erasistratus is reported to have been a very bold surgeon, not hesitating to excise portions of the liver and of the spleen. The invention of a metallic catheter is ascribed to him. Xenophon of Cos, a pupil of Erasistratus, is said to have been among the first to restrain hemorrhage from the limbs by tightly encircling the member with a ligature. Ammonius, surnamed *Lithotomus*, invented an instrument for crushing vesical concretions too large to be extracted through the ordinary incision—what would now be called a lithotome—and hence is erroneously accredited with anticipating Ovide in the invention of the lithotrite, an instrument for crushing stones without a cutting operation.

Celsus, Aulus.—From the time when the empire of the world was transferred to Rome until the reign of Augustus there appeared no surgical practitioner or writer of note until Aulus Cornelius Celsus, of whose numerous writings the eight books *De re Medica* are alone preserved. The last four books treat exclusively of surgery. He advises the amputation of limbs affected by gangrene. The method of lithotomy he describes is still regarded as of value in certain cases. He gives rules for the removal of cataract by depression, for forming an artificial pupil, and for the recognition and reduction of several varieties of hernia. The diagnosis

and treatment of fractures and lacerations he treats of judiciously and in detail. He is thought to have been the first to point out ruptures of the intracranial blood-vessels occasioned by fracture. In the twenty-sixth chapter of his fifth book occurs the remarkable passage in which he advises that the bleeding from a wounded vessel, if it can not be otherwise restrained, shall be controlled by two ligatures, placed one above and the other below the bleeding point. He recommended the ligature also in varices and hemorrhoids. It would be an endless labor, however, to particularize. Not only the value of his authorship, but the purity and elegance of his style, have made the work of Celsus classical and immortal. Aulus of Cappadocia practiced in Rome in the latter part of the first century. His instructions on catarrhism and on lithotomy are interesting; he opened hepatic abscesses and used the trephine for the cure of epilepsy. The doctor, the medical adviser of Trajan, was the author of some good observations on injuries of the head. Rufus of Ephesus is said to have been the first to be successfully an artery for an aneurism at the bend of the elbow caused by venesection. He left a treatise on diseases of the bladder. No great surgical writer appeared from the time of Celsus in that of Galen (c. 200), toward the close of the second century. He was a surgeon at Pergamum (c. 160), and afterward practiced his profession at Rome.

Aetlius, Alexander of Tralles.—After Galen, in the third century came Aetlius, who was a bold and successful surgeon. He recommended extraction for hard cataract, but cautiously, advising the operation only when the cataract was small. He also suggested arteriotomy in place of venesection in some cases, arguing that there was not risk of excessive bleeding since the hemorrhage might be controlled by cutting the vessel completely across. His name is associated with an operation for aneurism, revived by Syme of Edinburgh, and still occasionally employed, especially in cases of traumatic origin. Oribasius (380-400 A. D.) was the author of a valuable compilation of surgical knowledge, and alluded to the partial or bent fracture of the long bones of children (greenstick fracture)—an observation for which Malgaigne accredits Lanfranc, a surgeon of the thirteenth century. Aetlius (529 A. D.) was the first Greek medical man of prominence to embrace Christianity, and the bias of his religious ideas is clearly indicated in his writings. Alexander of Tralles (529 A. D.) appears to have been an independent thinker, and at the close of a long and useful career wrote from his own experience with such sound judgment that his work in twelve books is a valuable relic.

Probus, Apollonius, who was a professor at Alexandria about the time (640 A. D.) of his final subjugation by the Saracens, wrote a compendium of the healing art which is even more circumstantial than that of Celsus. The excellent translation by Adams, published by the Sydenham Society, has made the work familiar to English-speaking surgeons. In lithotomy he advised, after exploring by the rectum, an incision in the left of the raphe, or the modern lateral operation, instead of the median incision of Celsus. He discriminated aneurism by anastomosis, and performed ablation of the mamma, laryngotomy, and herniotomy in strangulation. He first treated of fractures of the patella. He was pre-eminent as an accoucheur, and is reputed to have devised the procedure of embryotomy. He was surnamed *Obstetricus*. He was the last of the Alexandrian school of any note.

Arabian Surgery.—In the seventh century, contemporaneously with the vast achievements and conquests of the followers of Mohammed, learning was gradually communicated to the Arabians, and for the next five centuries anything noteworthy in surgery must be looked for in this direction. Rhazes (852-932 A. D.) practiced and taught at Bagdad at the close of the ninth and beginning of the tenth century. He was the first to describe *spina bifida*. He cauterized the bites of rabid animals. He gave a better account of hernia than his predecessors. He seems to have had little confidence in ophthalmic surgery, for when he was old he had cataract, but could not be induced to submit to an operation. Haly Abbas lived at the end of the tenth century, and was a voluminous writer. In tapping for ascites he preferred to puncture in the linea alba, and he used cautery for hæmorrhoids of hæmorrhoids. Avicenna (980-1037 A. D.), educated in the schools of Bagdad, acquired an extraordinary distinction, but the most important to surgery among the Arabian celebrities is Albucares (1110 A. D.). The edition of his *Chirurgia*, by Channing of Oxford, is still consulted, and contains the most complete view there is of the knowledge of surgery that then existed. He seems to have

abused the actual cautery, and enthusiastically extols the surgical virtues of fire. He employed the cautery to suppress hæmorrhage, and styptics likewise, but also complete division of the vessel, and even the ligature. He was the first, apparently, to remark the occlusion of a divided artery by a coagulum. He practiced enterorrhaphy, and invented a probang for dislodging foreign bodies from the gullet, and an instrument for operating in lachrymal fistula. These and various other instruments he figures in his writings. After Albucasis arose two notabilities of the Saracenic school who were natives of Spain, yet wrote in the Arabic language. Avenzoar (1162 A. D.), a Jew, practiced at Seville in Andalusia, and his compendium entitled *Thaissy*, though mainly a compilation, contains some original matter. He describes abscess of the mediastinum, and a case of suppuration of the kidney with discharge of 14 pints of pus. He treats judiciously of fracture involving the hip-joint, and of wounds of the blood-vessels. His pupil, Averroës (1198 A. D.), a native of Cordova, achieved a great reputation. A manuscript of 336 quarto pages, by an unknown author, was discovered in 1863 in the library of the University of Madrid, which gives an extended view of the Arabic treatment of wounds, including shot wounds by missiles of iron and stone. In a prize essay by Dr. Don Antonio, entitled *Memoria sobre el Origen y Vicisitudes de la Terapéutica que han usado los Cirujanos españoles en las Heridas de Arma de Fuego* (Madrid, 1863), it is claimed that the nature and treatment of shot wounds are judiciously discussed in this parchment, and that it dates from the closing part of the fourteenth century, or shortly after the introduction of gunpowder in warfare. Should the date and authenticity of this manuscript be established, it would be the earliest treatise on shot injuries extant. Neither Arnold of Villanova nor Guy of Chauliac mentions these injuries, and priority in adverting to them has commonly been ascribed to the German surgeon Heinrich von Pflsprundt (1460 A. D.), whose manuscript, *Buch der Wundt-Artzney*, was printed in 1668 by Haeser and Middeldorpf.

Medieval.—For several centuries there is among the successors of the Greeks and Romans no name in surgery to arrest attention by association with improvements either in theory or practice. The only attempts worthy of notice are in connection with the schools established at Salerno and Monte Casino, which maintained their prestige until the thirteenth century, when they were eclipsed by the rising reputation of the schools of Bologna and Paris. Most of the Italian surgeons of the thirteenth century whose names have left any trace in the history of the art appear to have derived their knowledge from one or the other of these schools. The first of these in date is Rogerius of Parma (about 1206). His *Chirurgia Magna* was long a textbook in Italy. He practiced enterorrhaphy, even in cases of complete division of the intestine, attempting to unite the divided surfaces by direct apposition over a cylinder of elder-wood. His disciple, Roland Capelluti, professed surgery at Bologna (1264), and composed a voluminous commentary on the work of his preceptor—whom he far surpasses in erudition—citing the Greek classics as well as the works of the Arabians. In a case of hernia of the lung he excised the protruding part, and the patient survived. Another disciple of Rogerius was Jamerius, who is described by Guy of Chauliac as a brutal and eccentric surgeon, but is placed by Peter of Argelata among celebrated operators of his time. Great obscurity envelops the history, and even the names, of the Four Masters, to whom are ascribed some important improvements in surgery, especially a method of suture of wounded intestines which still holds a place in the art. According to Devaux, they were four monks living at Paris in the time of Lanfranc (at the close of the thirteenth century), devoting themselves to good works. According to others, they were four teachers of surgery, who professed in four languages—Magister Salernus in Latin, M. Pontus in Greek, M. Abdallah in Arabic, and Rabbi Elimus in Hebrew. Weber and others believe that Rogerius, Jamerius, Theodoric, and William of Salicet are the four teachers referred to under the designation of the Four Masters. The little evidence extant gives most plausibility to the first of these conjectures. Manuscript copies of their voluminous work on surgery existed in the seventeenth century at Avignon and at Paris, and some fragments are said to be still preserved in the Bodleian Library at Oxford; but the work was never printed, and the opinions of these skillful masters are known only through citations in the works of their contemporaries. Hugo of

Lucca (d. 1252) is regarded as the founder of the Bolognese school. He reduced a luxation at the hip of a year's standing in a man of twenty-five, and used alcoholic lotions largely as topical applications to wounds. After Hugo came Brunus of Longobucco, a professor at Padua (1262). He composed a *Chirurgia Magna*, and approved of dry dressings to wounds. Theodoric of Cervia, a pupil—and, according to Tiraboschi, a son—of Hugo of Lucca, expounded the views of his predecessors. He is accredited with having substituted soft and simple bandages and splints in fractures for the cruel appliances in vogue in his day. According to Guy of Chauliac, the Italian surgeons of this period may be classified in two schools. One, with Rogerius, Rolandus, Jamerius, and the Four Masters as its exponents, treated all wounds and ulcers by emollient fomentations and cataplasms; the other, in which Hugo, Brunus, and Theodoric were conspicuous, employed dry dressings or desiccating lotions. William of Salicet (b. at Piacenza in 1210) practiced in armies and at Cremona, Pavia, and Verona, and finally went to Bologna, and there (June 8, 1275) completed his work on surgery. He is the first Italian surgeon who treats at any length of the surgical affections of women. Gilbertus Anglicanus (1290) appears to be the first English writer on surgery. In 1271 Pitard founded the College of St. Côme at Paris, which was the origin of the Academy of Surgery that became so famous in later years. Pitard was a man of eminence in his day, and his observations on wounds of the head and on poisoned wounds are still remembered. Lanfranc, a Milanese and a pupil of William of Salicet, is generally regarded as the creator of surgery in France. He was the first to speak of the healing of wounds by "first intention." At this time flourished Master Jehan Ypermann (1295–1350), lately styled the father of Flemish surgery, whose manuscript treatise on the art was discovered and published as late as 1854 by the medical Society of Ghent. During the fourteenth century surgical science was dead in Italy. Rienzi states that Bartolomeo de Varignana dissected human bodies in 1290. Mondini de Lucei also publicly dissected at Bologna the cadavers of two women, braving the prejudices of his time, and published an anatomical work illustrated by wood engravings (1325).

Fourteenth and Fifteenth Centuries.—Early in the fourteenth century John of Gaddesden, after studying at Montpellier, practiced surgery with success at Oxford, and composed his *Rosa Anglica*. John of Arden flourished in Newark about 1350, and subsequently removed to London. He compiled voluminously, but a treatise on *fistula in ano*, published in 1588 by John Reed, is the only one of his writings that was printed. Guy of Chauliac practiced in Avignon in the middle of the fourteenth century with renown. In his writings is found the first mention of the Cesarean operation. Guy is esteemed a bolder surgeon than Lanfranc. Ackerman declares that his *Grande Chirurgie* embraces all of value written on surgery up to its epoch. Pre-eminence in surgical knowledge seems to have passed from Salerno to Bologna, and thence to Montpellier. The latter school, fostered by the neighboring papal court at Avignon, was enriched by manuscripts from both Spain and Italy. Guy described the use of weight-extension in fractures of the lower extremity (now commonly known as the "American method"), and treated indolent ulcers by binding on them a leaden plate. In the latter part of the fourteenth century the school of Montpellier rapidly declined. Both Italy and France were desolated by contending factions; the library of Guy was scattered. Balescon of Taranta, a Portuguese professor who succeeded to the chair of surgery, laments the loss of the works of Paulus, Rufus, and others. Balescon (or Valescus, as his name is sometimes Latinized) is said to have first advised the employment of mercurial ointment for the removal of lice and other parasitic vermin. Leonardo Bertapaglia (1429) is said to have practiced human dissections, and to have brought a certain luster upon the chair of surgery at Padua. He wrote on ulcers and wounds, and enumerates twenty-two kinds of punctured wounds by darts and arrows. He seems to have first described the tenaculum. Among other Italian surgeons who in some measure aided in the progress of surgery may be mentioned Guainerius, professor at Pavia, who wrote on diseases of the joints; his successor, Matthew of Gradi; and Bartolomeo Montagnana (1441), professor at Padua, who wrote on hernia, and first distinguished that variety of ventral hernia that protrudes through the linea alba. Arculanus also (1427) taught with credit at Verona and Ferrara, and devised several kinds of trusses and an instrument for extracting foreign bodies from

the ear. He ligated the jugular vein in tortoises and wrote judiciously of colicropion. *Messias Commens* was a surgeon in the Venetian army in 1493 at the invasion of Turkey VIII, and treated haemorrhoidal wounds with boiling oil, regarding them as poisonous. Antonio Benivento a Florentine oculician (1499) is probably the first writer treating systematically of morbid anatomy. He dissected two cases of ophthalmia, an affection which J. L. Petit is sometimes supposed to have first described. Holmich von Probenhoff, after participating in the great war in Poland in 1524, wrote his *Deich der Wundt-arterien*, containing an early observation on shot wounds. He describes a rhinoplastic operation, anticipating Tagliacozzi by a century. In 1599 Cullen, a French surgeon in favor with Louis XI of France, performed lithotomy successfully on a child without external, and this operation, previously abandoned in the worst quacks, became a part of the legitimate practice of surgery. Paracelsus (p. 15) noted in his time both as practitioner and author, was the introducer of many reforms.

Sixteenth Century.—With the revival of letters and of the natural sciences in the sixteenth century a new era dawned on surgery. Investigation of anatomy in the true sense was undertaken by Vesalius (1514-44), Fallopius (1522-42) and Rueschius (1580-79) wonderfully succeeded this founder of modern anatomy. Patients of Aspernabende (1537-1519), a pupil of Fallopius, was the teacher of William Harvey (1578-1657), the immortal discoverer of the circulation of the blood. Gasparo Aselli (1581-1630) followed with the discovery of the lymphatic vessels. The way was thus paved for advances in surgery, which, illuminated by science, became a worthy pursuit for men of talent and education.

Paris.—Presided by John di Vigo (1530), who still believed shot wounds poisonous, and by the Swiss surgeons Huse von Gersdorff (1529) and Felix Wirtz (1570), who have left original descriptions of value, the latter being reputed the first surgeon who ventured to amputate in the thigh, appears Andreas Paré, the founder of the modern French school, and reckoned the ablest of early army surgeons. If not the inventor, he was the restorer of the art of securing arteries by ligature after amputation—an advance which alone sufficed to secure for him immortality. Though originally a barber-surgeon, he became the counselor of four kings of France, and acquired such esteem that "his mere presence in a besieged town was enough to reanimate the garrison." His complete works were collected and published by his pupil, Guillemeau, in 1602, and have passed through many editions in many languages. Pupil of Guillemeau succeeded Paré in his high dignities, and received great praise from his contemporaries. Mercurius succeeded him with instructing ambulance-wounds, an advance in military administration usually ascribed to Larrey in the nineteenth century. Guillemeau, besides editing Paré, distinguished himself in operative midwifery. In Italy at this period appeared several treatises on shot wounds. Maggiori wrote the *Falunco Bombardamento di Sceloporum Locutione* at Bologna in 1522. The work of Leonardo Botai on the cure of shot wounds (Lyons, 1560) is, after the writings of Paré, the most valued of the treatises on shot wounds of this period. Caranus, of Milan (1573), and Heremgarus, of Carpi (1580), published original but little-known treatises on injuries of the head. Marius Sanctus, of Barletta, near Naples (1550), suggested improvements in lithotomy, and Tagliacozzi published in 1587 at Venice his treatise on plastic operations. The English surgeons of this period are not conspicuous. Thomas Gale, who served in 1544 with the army of Henry VIII. at Montreuil, published (1592) the *Institution of a Chirurgeon* and a treatise on gunshot wounds, which had the merit of denying the poisonous nature of such injuries. J. Hall (1591) also treated of shot wounds. John Wastell, who served in France in 1593, and was afterward surgeon-general of the East India Company's forces, published a *Military and Domestic Surgery*. William Clowes, a naval surgeon, wrote (1591) a *Practical Practice in Rurselaga by Gunpowder*. Peter Lowe, who served in France and Flanders, printed (1597) an *Army Surgery* that went through several editions. The work of Doctore (alias Quercetanus) on shot wounds (1579) was translated into English. In Germany A. Schenckius, professor at Presburg (1531-96), compiled a voluminous work of rare surgical cases, which remains a mine of interesting information.

Seventeenth Century.—In the seventeenth century the impulse given to the sciences by the diffusion of learning led to further improvements. Gasar Magalini, professor at Ferrara, simplified the treatment of wounds. His work (*De*

Rea Meditacione Vulnerum, Venice, 1616) is still consulted with advantage. Valerius Hildanus, of Bern (1560-1634), by some styled the father of German surgery, was a man of great attainments, but along to old prejudices and unsympathetic with radical surgery. Richard Wiseman, surgeon to Charles II., has often been styled the true father of English surgery, but his *Several Chirurgical Treatises* (1619) really contain no positive addition to the knowledge of the time. John Brown, another chirurgeon in ordinary to Charles II., a naval surgeon, published a *Treatise on Wounds, general and particular*, and a *Treatise of Gunshot Wounds*. In London in 1678—a work deduced from his practice in the navy in the Dutch war of 1665, in which he was severely wounded. Holland, destined to liberty in this century, furnished several good surgeons who promoted their art. Johann J. Rea, of Leyden, was probably the most successful lithotomist in record. Philp (1648-1734) was distinguished for devising a new plan for internal sinuses. Roonhuyzen (1690), by his operations for very neck, may be regarded as the inventor of tracheotomy. Peter Verduyn, of Amsterdam, proposed (1698) an important modification in the flap method of amputating the leg. In France the tourniquet was first used in amputations by Morel at the siege of Rouen (1674). Pierre Jaques improved the manual procedure of lithotomy, while Bellac (1696) deserves credit for denouncing the abuse of tents and complicated dressings then in vogue.

Nineteenth Century.—France. In the eighteenth century we find great advances in surgery, and the French surgeons in the front rank. Jean Louis Petit (1674-1769) occupies a proud prominence among the early educated writers on the art. His treatise on diseases of the bones is classic; his work on general surgery is still consulted with profit. He devised the now ubiquitous instrument for a century an essential appliance in amputations. Le Dron (1686-1773), with less genius, was an original and successful author. His copious writings abound in practical wisdom. Pierre J. Desault (1744-83) is one of the great names in surgery. He was the first who taught systematically surgical anatomy. His improvements in the treatment of fractures are illustrated in the everyday practice of the present time. He substituted straight supinating knives for the formidable sickle-shaped weapons previously employed. He improved the procedure for ligating arteries, and proposed the plan for the cure of aneurisms by distal ligature that bears the name of "Desault's method." Dominique Arcl, of Toulouse (1678-1743) secured a permanent niche in the annals of surgery by first proposing the proximal ligature of the main trunk in aneurisms. The institution of the Royal Academy of Surgery in Paris (1731) had great influence on the advancement of surgery not only in France, but throughout the world. Its *Mémoires*, composed of contributions from the most eminent men, constitutes a rich mine of information which has been diligently worked by many compilers, for the most part with worthy acknowledgment. Merit may be regarded as the leading authority on wounds of the abdomen. David, the central, Bellac, well known by his name, Le Cat, the lithotomist, and Moreau, the founder of the practice of excision or resection of joints, are conspicuous among the specialists. Besides these academicians were many French writers who held an honorable place in surgical literature. Baron Percy, whose invaluable manual for the army surgeon was published in 1792, may be esteemed the foremost military surgeon between Paré and Larrey. The name of Xavier Bichat (1771-1802) closes this era in French surgery. This illustrious founder of general anatomy, the great genius who accomplished so much in his short span of life, commenced his career as a surgeon, and his earlier works are unimpaired editions of the teachings of his great preceptor, Desault.

Great Britain.—In Great Britain surgery attained great eminence in this century. William Clowes (1668-1732), Samuel Sharp (1700-68), Percival Pott (1713-88), W. Bromfield (1719-82), Benjamin Bell (1740-1806), and the brilliant John Hunter (1763-1793), all secured a permanent place in the literature of surgery, while the illustrious John Hunter (1728-93), a philosopher as well as an anatomist and surgeon, is justly ranked with the greatest minds that have graced the profession. Moore (1697-1767) is indissolubly associated with the birth and fame of the Edinburgh school. C. White, of Manchester (1770), revealed the achievements of the Marquis in France in excising the larger joints.

Continental Europe.—In Italy, Scarpa (1747-1823), by his researches on hernia and aneurism, attained a high reputation. In Spain the name of Gibberson is eminent.

Hendrik Callisen (1740-1824) was the most prominent surgeon of Denmark of his time. In Germany, Heister (1683-1758) wrote a system of surgery that was translated into many languages, and still enjoys a certain repute; and the encyclopædic Albert von Haller (1708-77) was Professor of Surgery at Göttingen.

United States.—Dr. William Shippen, of Philadelphia, in 1763 first delivered lectures on anatomy and surgery, and the first medical school in America (the University of Pennsylvania) was founded by Dr. Morgan in 1765. Dr. John Warren (1753-1815), Professor of Surgery in Harvard College, and James Tilton (1745-1822), a surgeon of the Revolutionary war and afterward surgeon-general of the army, were likewise eminent.

Nineteenth Century.—Europe.—At the beginning of the nineteenth century French surgeons were still in the foreground. Jean Dominique Larrey (1776-1842), the friend of Napoleon I., was an almost undisputed authority in military surgery in his time. Boyer (1757-1833) prepared a systematic treatise on surgery that was long a standard text-book. Delpech (1776-1832) taught surgery at Montpellier with nearly equal reputation. Dupuytren (1777-1835) may be regarded almost as the founder of a school. Many of the great French surgeons of the middle of the century were his pupils—Vespeau (1795-1867), Malgaigne (1806-65), Jobert (1799-1868), Vidal (1803-56), Nélaton (1807-73), and Goyrand of Aix; Roux (1780-1854) was Dupuytren's contemporary and rival. It would be endless to enumerate the eminent surgeons of the time. Lisfranc (1788-1847) acquired an unrivaled distinction in operative surgery. Cloquet (1790-1855) was renowned as a clinical teacher. Civiale (1794-1867) originated and Leroy (1798-1861) improved lithotomy. Bonnet of Lyons (1809-58) was among the first to treat in a scientific manner of diseases of the joints. Follin (1823-67), Guérin, and Sédillot, also were distinguished. In Germany the advance of surgery, if not as brilliant, was relatively as decided. Kern, of Vienna (1760-1829), Rust, of Berlin (1775-1840), von Walther, of Munich (1782-1842), Graefe, of Berlin (1787-1840), Konrad J. M. Langenbeck, of Göttingen (1776-1850), Dieffenbach, of Berlin (1795-1847), C. von Textor, of Würzburg (1782-1860), all aided the progress of surgery by their writings, and several of them made important improvements in the art. At the beginning of the century the Vienna school in ophthalmology was pre-eminent. G. J. Beer (1762-1821) was perhaps its most distinguished representative. The name of Albrecht von Graefe, of Berlin (1828-70), is indissolubly associated with the modern methods of treating glaucoma and cataract. The great illustrator of military surgery in Germany, the illustrious Louis Stromeyer (1804-76), the worthy successor of Paré and Larrey, was one of the founders of modern conservative surgery in cases of injury. Volkmann (1801-77) and Nussbaum (1829-90) stand high in the annals of German surgery. In Belgium, Seutin devised the method of treating fractures by starch bandages, which has led the way to the plaster treatment of the present time. In Italy, Assalini (1765-1840) and Porta acquired distinction. In Great Britain a succession of surgeons of the first merit rivaled their French contemporaries. The London school points with pride to Cline (1750-1827), to Abernethy (1764-1831), to Sir Astley Cooper (1768-1841), to Wardrop, Earle, Stanley, Travers, Hodgson, Lawrence, and Aston Key; to Sir Charles Bell; to the ophthalmic surgeons Tyrrell, Saunders, and Dalrymple; and to the illustrious Sir Benjamin C. Brodie (1783-1862). In Ireland, Colles, Carmichael, Jacob, Bellingham, and Tufnell are known by original researches, and Cusack, Crampton, R. W. Smith, and Maurice Collis earned high reputations. Scotland may boast of Liston, of Miller, of Syme, of Spence, and of Sir J. Y. Simpson, the obstetrician who recommended acupressure as a substitute for the ligature, and introduced chloroform as an anæsthetic. The annals of British surgery in the century are further advanced by two names that will always be remembered in the front rank of military surgeons—John Hennen (1770-1829) and G. J. Guthrie (1785-1856). Worthy contemporaries of Larrey, their works will ever be read with reverence by students of army surgery. The names of Fergusson, Callender, Savory, and many others, now deceased, add lustre to the annals of British surgery, while Paget, Erichsen, Henry Thompson, Spencer Wells, Hutchinson, Holmes, Lister, and many more worthily sustain the reputation of their predecessors.

United States.—In the U. S. in the nineteenth century great advances have been made in practical surgery. A

pupil of John Hunter, Philip Syng Physick (1768-1837), is often styled the father of American surgery. He left no work to record his vast experience, but his views were to some extent recorded by his nephew, John S. Dorsey (1783-1818), the author of the first systematic treatise on surgery published in America. John Collins Warren, of Boston (1778-1856), wrote a treatise on tumors, and was the first to perform (Oct. 16, 1846) an operation of importance on a patient anesthetized by ether. Valentine Mott (1785-1865) acquired an immense fame by his daring operations on the arteries. According to Prof. Gross, "no surgeon, living or dead, ever tied so many vessels, or so successfully, for the cure of aneurism, the relief of injury, or the arrest of morbid growths." Benjamin Winslow Dudley (1785-1870), of Kentucky, had marvelous success as a lithotomist, and was noted for his dexterity in bandaging. Ephraim McDowell (1771-1830), of Kentucky, first performed ovariectomy (1809). William Gibson (1788-1866), of Philadelphia, was the first to tie the common iliac artery and to successfully perform the Cesarean operation twice on the same subject. Nathan Smith (1762-1828), of New Haven, was a bold surgeon of indomitable industry and great versatility. Thomas D. Mütter (1811-59) was noted for his skill in the treatment of deformities. He bequeathed a valuable surgical museum to the Philadelphia College of Physicians, with a liberal endowment fund. George Hayward, of Boston (1791-1863), J. Rhea Barton (1796-1871) and George W. Norris (1808-75), of Philadelphia, and J. Mason Warren (1811-67), of Boston, were able hospital surgeons, whose contributions to the literature of the art are of permanent value. Other eminent names are those of Gross, Pancoast, and Agnew, of Philadelphia; of Van Buren, Hamilton, and Post, of New York; of Nathan R. Smith, of Baltimore, Eve, of Nashville, Hodgen, of St. Louis, and Bigelow, of Boston.

Advances in the Art.—The boundaries of nationality seem to be vanishing from the domain of surgery. With marvelously increased facilities of intercommunication, all advances are speedily known throughout the civilized world. At no former period, assuredly, was there greater scientific activity. One result of the emulative ardor with which surgery has been latterly cultivated is the prevalent tendency to pursue special branches of the art. Ophthalmology, invoking the aid of physical science, has been revolutionized, and in many other directions light has been thrown upon branches of surgery until lately enveloped in the deepest obscurity. The discoveries and improvements in surgery in the nineteenth century are not inferior to those of any preceding age. The practical use of anæsthetics, introduced in the shape of ether-inhalation by Morton in 1846, and by the use of chloroform by Simpson in 1847, constitutes an epoch-making advance in the art, while the employment of cocaine for securing local anæsthesia is a discovery of real though minor importance. The introduction of ovariectomy (1809) by McDowell, of lithotomy (1822) by Civiale, and of litholapaxy (1878) by Bigelow, are improvements of the first order. The extensions of reparative surgery to the relief of cleft palate, vesico-vaginal fistula, and a great variety of deformities, have been of much value. The employment of metallic sutures and ligatures (Levert, 1829), of immovable apparatus in the treatment of fractures (Seutin, 1842) and spinal affections (Sayre, 1877), and of manipulation in the reduction of luxations (W. W. Reid, 1855), are most important innovations. The bloodless method of Esmarch (1873) and the antiseptic method of Lister (1869) are of far-reaching application. The great advances made in the treatment of diseases of the joints, of blood-vessels and nerves, of the brain and spinal cord, eye, ear, larynx, thoracic and abdominal viscera, urethra, and rectum, and of outgrowths and tumors, are most creditable.

It would be impossible within the limits of this article even to enumerate, still less to describe, the many triumphs of the surgical art which have been won during the latter half of the nineteenth century, but a few of them may be briefly referred to. Beginning with the external integument, the introduction of *skin-grafting* has rendered it possible by the transplantation of small portions of cuticle, taken from the patient himself or borrowed from other individuals, to secure the healing of large ulcerated surfaces after burns or other injuries, which formerly would have been abandoned as totally incurable. The dread which the older surgeons felt in dealing with *nerves* has been replaced by a boldness which enables the modern operator to sew or splice nerves which have been accidentally severed, thus restoring function and preventing loss of power, and on the other

lived in intense intractable neuralgia by nerve-stretching or excision; and for this purpose surgeons have not hesitated to open the skull or vertebral column, so as to attack the diseased nerve directly at its origin from the base of the brain or spinal cord. Operations on the blood-vessels have become so much safer since the general adoption of aseptic methods that the surgeon now has without fear the largest vessels when they are accidentally wounded, those presenting directly from hemorrhage, while the lessened risk attending the ligation of large arteries enables him to attack arterial aneurisms which a few years since were not thought amenable to surgical interference. Aneurisms of the thoracic aorta and innominate artery are successfully treated by simultaneous ligation of their principal branches; a subclavian aneurism has been successfully dissected out and removed bodily, as if it had been a solid tumor; and even abdominal aneurisms have been cured by firm pressure maintained for many hours while the patient was kept in a state of anesthesia, and in at least one instance by abdominal section and the introduction into the aneurismal sac of a coil of silver wire.

Diseases of the Joints.—In the treatment of these affections surgery has made marvellous progress. It is no longer thought essential, unless in exceptional cases, to amputate the thigh for scrophulous or tuberculous disease of the knee (knee swelling); but the surgeon cuts out the offending articulation, preserving a useful limb, or in milder cases simply opens the joint and scrapes out the diseased tissue, or even effects a cure by the injection of iodoform and glycerine. Hip disease is no longer the prohibition of surgery which it was; it is often curable in its milder forms by fixation and extension, followed by the use of judiciously planned orthopædic apparatus, and in its worst forms, osteotomy, or even excision, is successfully resorted to, and the patient is often restored to the duties of an active life with a limb somewhat shortened, but strong and enduring. Orthopædic surgeons deal with the distressing deformities due to rickets with a boldness which a few years since would have been thought almost criminally reckless. Knock-knees and bow-legs are straightened by cutting across the deformed bones with an osteotome or chisel, and the limbs are encased in plaster-of-Paris bandages with confidence that they will quietly and surely regain their firmness in their improved position. Boleping or inveterate club-foot is successfully treated by boldly cutting through and separating all the contracted tissues, or even by cutting out the malshaped bones thus making the foot both symmetrical and useful. Ununited fractures and false joint, after an arm or a leg is broken, are no longer divided as they were by our ancestors; the surgeon cuts boldly down upon the seat of injury, drills the bones, and joins them with a thick silver wire, or secures them with a silver splint directly applied to the fragments themselves and held in place by screws, and then closes the wound with the expectation that it will heal soundly over the inserted metal, which will supply the needed firmness to the broken bone and remain indefinitely, quietly buried in the surrounding tissues.

Surgery can no longer be considered as an equivalent term for external medicine, for the modern surgeon opens without hesitation all the great cavities of the body, explores with sight and touch the condition of the internal organs, and subjects them to such operative measures as may seem indicated. The skull is opened to permit the arrest of intracranial bleeding, the evacuation of intracranial abscesses, and the removal from the brain of tumors the exact site of which has been determined beforehand by the rules of cerebral localization. The thorax is cut into for the relief of emphysema, or even morbid conditions of the lung itself, and after evacuation of the pleural contents reaccumulation is prevented by securing free drainage, cutting away, if necessary, considerable portions of the ribs in order to permit ventilation and healing.

Abdominal surgery has perhaps made more striking progress than any other department of the art; hardly any organ of the abdominal cavity but is subjected to exploration, and, in cases otherwise incurable, to complete or partial extirpation. The surgeon cuts into a kidney, removes stones from its interior, strikes it into its proper place when it is displaced, and when hopelessly disorganized removes it entirely from the body. The spleen is excised, as is the pancreas; wounds of the liver are sewed up or plugged in prevent hemorrhage; stones are removed from the gall-bladder, or the latter is itself removed, or, if inclusion of the duct prevents the natural escape of bile into the intestine, an artificial

duct passage is established into a neighboring portion of the bowel. Wounds of the stomach and bowel are closed by sutures, malignant tumors of these organs are boldly cut away, and the continuity of the alimentary canal is re-established, sometimes after the removal of many inches or even several feet of intestine. Suppurative inflammation of the appendix vermiformis is now known to be the multiple process in many of the cases formerly known as typhoid, and is successfully dealt with by prompt excision of the diseased organ.

The triumphs of special surgery—ophthalmic, nasal, laryngeal, cysto-urethral, and gynecological—are no less brilliant than those which have been enumerated. The great success which attends surgical operations at present is to be attributed to a combination of causes, of which the discovery of anesthesia and the introduction of aseptic and antiseptic methods of wound-treatment are the most prominent; but great importance is to be attached also to the general diffusion among practitioners of surgery of sound physiological, pathological, and therapeutic knowledge, thus enabling the surgeon not only to operate with facility and protect the wound from injury, but also judiciously to treat the patient after the operation and thus promote speedy and permanent recovery. See *DIAGNOSIS*, *GYNECOLOGY*, *OPHTHALMOLOGY*, etc.

Ku'rieste [from the Dutch (S. African) name, *K. P. suricate*], or **Zenick** [Anglicized form of native (S. African) name]: a carnivorous viverrid mammal of South Africa, the *Suricata suricatta* or *S. leucodactyla*. It is about 12 inches long, with a tail a little more than half that length, and closely resembling the lemming; of a grayish-brown color, tinged with yellow, and with faint darker bands across the back. Its habits are nocturnal, it dwells in burrows, and is often domesticated, being very useful as a destroyer of vermin.

Muriam': See *MIRIAM (Hebrew)*.

Murmellet: See *MURMEL*.

Surname: See *NAME*.

Surplice [from O. Fr. *surplis*, *surplis* < Late Lat. *superpellicion*; *super*, over + *pellis*, a fur garment, pellicie], a clerical garment worn in churches by priests and all clerics, and worn by acolytes and choir-boys. It is considered to be a clerical style or a modification of the alb, and dates back to the twelfth century. It is worn by clergymen of the Church of England during the celebration of service, and at the performance of all ecclesiastical offices, as also by clergymen of the Danish, Norwegian, and Swedish churches, but by them only during the celebration of the Lord's Supper. The use of the surplice, however, was strongly objected to by the Calvinistic and Zwinglian Reformers on the Continent and by the Puritans in England, who regarded this vestment as a relic of popery and made it the subject of vehement denunciations. Both in the Church of England and in the Protestant Episcopal Church in the U. S. its use has become general, and all connection in the popular mind of the surplice with Romanizing tendencies has passed away.

Revised by W. S. Pray.

Surrey: inland county of England, bordering N. on the Thames, which separates it from Middlesex; area, 359 sq. miles. It is intersected from E. to W. by a range of low hills (its highest point, Boxley Hill, being 889 feet), which slopes gently northward in the Thames, while to the S. the ground is more elevated and broken. In the northern part the soil is very fertile; in the southern it consists mostly of clay, chalk, and iron-sand; in the whole western part the land is heath. Wheat, hops, and vegetables are raised; hogs and poultry are extensively reared. Near London manufacturing industry is carried on. The county contains much wood, and the beauty of the scenery and the facility of communication with London have attracted many residents to Surrey, which is consequently studded with mansions and villas. Pop. (1891) 1,739,871.

Surrey, Henry Howard, Earl of; soldier and poet; b. about 1610; was the eldest son of Thomas Howard, Duke of Norfolk; passed his youth at the court of Henry VIII., and was one of the most accomplished noblemen of the time. In 1544 he commanded the English forces in France; was made field-marshal, and subsequently governor of Boulogne. In Jan., 1546, he suffered a reverse at St. Etienne, in consequence of which he was recalled and committed to the Tower, from which he was soon released, but in December was again arrested upon charge of treason for having

quartered the royal arms upon his escutcheon with the design of securing for his family the honor of the regency. Upon his trial he proved conclusively that he had a right to bear these arms together with his own, but was notwithstanding condemned, and beheaded upon Tower Hill, Jan. 21, 1547. His works consist of sonnets, amatory poems, elegies, paraphrases of the Bible, and translations of the second and fourth books of the *Æneid*. They present the earliest instances of the use of blank verse in English poetry, and have been several times republished, the latest edition being G. F. Nott's (1871). Revised by F. M. COLBY.

Surrogate [from Lat. *surrogatus*, perf. partic. of *surroga*, put in another's place, substitute; *sub*, under + *roga're*, ask]: one appointed as a substitute for another; and particularly an officer appointed to act in the place of a bishop, or of a judge, in matters relating to marriages and to probate jurisdiction. In England, since the abolition of the probate jurisdiction of ecclesiastical courts, and the establishment of a civil court of probate, the surrogate's principal function is dispensing licenses to marry without banns. He is prohibited by statute, unless "a qualified practitioner," from preparing for a fee any papers on which to found a grant of probate.

In some of the U. S. the term is employed to designate the officer upon whom probate jurisdiction is conferred. It is a survival from the colonial period, during which the governor of a colony was vested with full authority and jurisdiction over matters of probate, but exercised them through local delegates or appointees. The Supreme Court of Massachusetts declared in an early case that, before the Revolution, the judges of probate were considered as surrogates of the Governor and council, who derived from the royal charter the authority to prove wills and to grant administration. In New York the title of surrogate seems to have been first assumed by the Governor's delegate shortly after 1702. Later the Governor appointed a delegate in each county to act in his stead in probate affairs; and from that period to the present, with the exception of a few years, the county officer exercising probate jurisdiction has been known as surrogate. In New Jersey probate jurisdiction is vested in the orphan's court, of which the surrogate is a subordinate officer. In other States the courts exercising such jurisdiction bear various titles, such as probate courts, parish courts, county courts, or courts of the ordinary. As a rule, they are tribunals of limited jurisdiction, whose organization, procedure, and authority are prescribed by statutes, which should be carefully examined. It is generally declared that the surrogate, or corresponding officer, of the county in which the deceased had his legal residence at the time of his death shall have exclusive jurisdiction of administering his estate, although provision is made for granting letters of administration in foreign States, where such a course is necessary to the control of property in such States.

In some jurisdictions surrogates or probate courts have the power to appoint guardians for infants and imbeciles, to hear and determine disputes affecting estates before them for administration, to entertain and dispose of proceedings for the sale of real estate, and even to administer the estates of insolvent debtors. As a rule, these courts do not possess a general equity jurisdiction. In some States they are not allowed to exercise any equity powers, but in others it is held that where an estate is in settlement before a court of probate, and an equity arises between the persons interested in such estate, the court may exercise the fullest equity powers if necessary to do justice to all parties.

FRANCIS M. BURDICK.

Surveying [from Anglo-Fr. *surveier* : O. Fr. *surveoir* < Lat. *supervide're*, oversee, look over; *super*, over + *vide're*, see]: the art of measuring land for the purposes of determining areas, locating lines, and making maps. Surveying is supposed to have originated in Egypt, where property lines were annually obliterated by the inundation of the Nile, and its theory was then identical with geometry (Greek, *γῆ*, land + *μετρον*, a measure), which still furnishes the most important part of the theoretical principles.

Plane surveying is confined to areas so small that the surface of the earth may be regarded as plane, the curvature being inappreciable. It is divided into land-surveying, whose object is the determination of property lines and areas of fields; topographical surveying, which produces maps showing the undulations of the surface, the forests, swamps, and waters; hydrographic surveying, which locates

rocks, shoals, and all the features of bays and rivers; mining surveying, which locates the underground passages and shafts of mines; railway surveying, which establishes the best routes and grades for railway lines; and city surveying, which deals with streets, sewers, and water-supplies. Geological surveying notes the outcrops of rock formations, and lays them down on topographical maps, the field operations being usually of the nature of a rough reconnaissance.

Geodetic surveying extends over areas so large that it is necessary to take into account the curvature of the earth. For this branch of the subject, see the articles COAST AND GEODETIC SURVEY AND GEODESY.

Instruments.—The Gunter's chain of 66 feet, the engineer's chain of 100 feet, and tape-lines of various lengths are used for measuring distances, and it would be possible by these alone to obtain all the results required in ordinary plane surveying. By the use of the compass and transit, however, for measuring angles, many distances can be computed from a few measured ones, and the work thus greatly expedited and economized. The compass determines the bearings of lines with respect to the magnetic meridian, while the transit measures angles on a graduated limb. The theodolite, of which an illustration is given in the article HYPSOMETRY, is a form of the transit used in Great Britain. Leveling instruments and rods (see LEVELS AND LEVELING) are needed for determining elevations and differences of heights. In topographical work the plane-table and stadia-rods are used in connection with a triangulation, distances being measured by the spaces intercepted on the stadia-rods by wires in the telescope. See STADIA MEASUREMENT AND PLANE-TABLE.

Chain-surveying.—A few elementary problems in the determination of distances and areas by means of linear measurements alone may here be noted, but others in great variety will be found in treatises on surveying. Instead of using a chain the distances may be approximately found by pacing, or by walking over the lines, and counting the steps, the length of a step being first ascertained by going over a distance which is accurately known.

Two methods of finding the distance AX across a river are shown in Fig. 1. By the first method a parallelogram,

FIG. 1.

$ABCD$, is laid out, AB being a prolongation of AX ; then E is marked on AD at its intersection with CX . The distances AB , AE , DE being measured, the distance AX is computed by multiplying together AB and AE , and dividing the product by DE . By the second method XA is produced to B , and a stake, C , placed at any convenient point; then D and E are taken on BC and AC , so that they are in line with X . The distances AB , BD , DC , CE , and EA being measured, the distance AX is equal to

$$\frac{AB \times AE \times CD}{BD \times CE - AE \times CD}$$

which will be somewhat simplified if D be taken in the middle of BC .

A method of finding the length of an inaccessible line, XY , is shown in Fig. 2. A stake is first placed at any convenient point A , two stakes, B and C , at points on AX and AY , and a fourth stake, D , so as to make $ABDC$ a parallelogram. Then E and F are placed on BD and CD at their intersections with CX and BY respectively. The distances AB , BD , DF , and EF being measured, the distance XY is equal to

FIG. 2.

$$\frac{AB \times BD \times EF}{DE \times DF}$$

The area of a field, as *ABCDE* in Fig. 3, may be found by dividing it into triangles by either of the methods

Fig. 3.

shown, measuring all the lines, and then computing the area of each triangle separately. To find the area of a triangle whose three sides are known, add the three sides together, and take half the sum; from the half sum subtract each side separately, multiply together the half sum and the three remainders, and the square root of the product will be the area.

A map of an island or irregular field, as in the second diagram of Fig. 3, may be made by staking out a polygonal area *ABCDE*, and measuring either its diagonals or the distances to a central point. Then perpendicular lines, called offsets, are set off from each side to the boundary and their lengths measured, thus giving all the data for mapping and computing the area.

Compass-surveying.—By means of the compass the angles or bearings which each line makes with the magnetic meridian are read, and thus a smaller number of linear measurements is required. For instance, in the case of Fig. 1, the line *AE* may be measured, and the bearings of *AX*, *AE*, and *EX* be read; then the angles *EAX* and *AEX* are known, and the distance *AX* can be computed by the rules of trigonometry.

The area of a field is determined in compass-surveying by measuring the lengths and bearings of the sides. For example, for the case shown in Fig. 4, the field-notes would be as follows:

LINE.	Bearing.	Distance.
<i>AB</i>	N. 52° E.	532 feet.
<i>BC</i>	S. 21° E.	214 "
<i>CD</i>	S. 31½° W.	389 "
<i>DA</i>	N. 61° W.	362 "

From these data the distances *Ab*, *Ac*, *Ad*, called latitudes, and the distances *Bb*, *Cc*, *Dd*, called departures, are computed, and from these, in turn, the areas included between each line and its projection on the meridian *NS*. Then the area of the field is the sum of the areas *BbC'c* and *CcDdD'*, diminished by the sum of the areas *BbA* and *DdA*.

The method of balancing the latitudes and departures so as to eliminate errors of observations, and the computations of areas by means of double-meridian distances, given in most text-books on surveying, was perfected by David Rittenhouse (1732-96), and was formerly called the Pennsylvania method.

On account of oscillations in the forces of magnetism and of local attractions the compass is not an accurate instrument, and should be used only for rough reconnaissance or for farm surveys, where precision is not important. In all town or city work, as also in the surveying of railways and mines, the transit is generally employed for the direct measurement of angles.

Topographical Surveying.—A topographical survey of a region embracing more than a few square miles should be based on a triangulation which locates the positions in latitude and longitude of a number of stations. Then, starting from these stations, lines are run in various directions, and the location of roads, houses, streams, and other features, is made by offsets or by stadia sights. Levels are also run by which the contours or lines of equal elevations are determined, and thus a picture of the relief of the surface may be obtained. Rough topographical work, much of which is sketching, may be done for \$5 per square mile, but good work will cost four or five times as much. Photography is an aid in this class of work, views being taken from different points which enable the contours of the surface to be sketched in the office. See also TOPOGRAPHY.

In the survey of a railway topographical work is done on each side of the line, and this is necessarily of a precise character so as to enable computations of excavation or comparative estimates of the cost of different locations.

Public-land Surveys.—The public lands consist of tracts of territory that belonged to the U. S. after the Revolution, together with all ceded by individual States soon after the formation of the Constitution, with the additions since made by treaty with Indians or by conquest. In 1802 Col. Mansfield, then surveyor of the Northwestern Territory, inaugurated a plan, which with slight alteration is still in use, for surveying and recording such portions as were offered for sale. Its general features are as follows: The entire public domain is first divided into parts called land districts, each of which is put in charge of a surveyor-general, who controls all the surveys in his particular district. In each district a meridian-line is run, extending through the entire district, and from some point of this meridian an E. and W. line is run, which also extends through the district. These lines are determined astronomically, and when located serve as axes to which the subdivisions of the district are referred. Parallel to the axes, and on each side of them, other lines are run 6 miles apart, dividing the whole territory into squares, each containing 36 sq. miles, and called townships. To take into account the obliquity of the meridians, suitable offsets are made in accordance with an established system. The townships lying between two consecutive meridians 6 miles apart constitute a range, and the ranges are numbered from the principal meridian, both E. and W. In each range the townships are numbered both N. and S. from the principal E. and W. line. Thus if a township lies 12 miles E. of the principal meridian and 18 miles N. of the principal E. and W. line, it is called township 3 N., range 2 E. Each township is divided by meridians and E. and W. lines into squares having (as near as may be) a mile on each side. These are called sections, and each contains approximately 640 acres. The sections of a township are numbered from the northeast corner, running along the northern tier of sections to No. 6, thence backward to section No. 12, which lies exactly S. of No. 1, and so on alternately, running from right to left and from left to right, to the southeasterly corner, which is No. 36. The four middle sections are numbered respectively 15, 16, 21, 22. In some of the Western States section No. 16 is set apart for school purposes.

LITERATURE.—Among the numerous text-books on surveying may be mentioned Bellows's and Hodgeman's *Manual of Land Surveying*, Gillespie's *Treatise on Surveying*, Johnson's *Theory and Practice of Surveying*; and on railway surveying, Searles's *Field Engineering* and Shunk's *Field Engineer*. A journal published by the German Association of Surveyors since 1872 is *Zeitschrift für Vermessungswesen*, which is mainly devoted to precise methods.

MANSFIELD MERRIMAN.

Surveys, Geological: 1, systematic investigations of the character, arrangement, and distribution of the rock formations of a district; 2, state organizations or bureaus for the conduct of such investigations. In 1823 the Legislature of North Carolina provided for the geological survey of the State by Prof. Denison Olmsted, appropriating the sum of \$250 a year for four years. In 1830 Massachusetts followed the example of North Carolina, making a somewhat larger appropriation, and placing Prof. Edward Hitchcock in charge of the work. Between 1830 and 1840 similar surveys were instituted in Tennessee, Virginia, Maryland, New Jersey, New York, Pennsylvania, Maine, Ohio, Michigan, Delaware, and Kentucky; and before 1895 all the States of the Union E. of the Great Plains, as well as California and Oregon on the Pacific coast, had made similar provision for the investigation of the rocks and minerals within their borders. Some States, after a few years of continuance, abandoned the work, or it was discontinued for a period. Others completed the investigations according to the original plan, and the results were communicated to the citizens in a series of final reports. Pennsylvania completed the survey first planned, and then after a lapse of years executed a second survey upon a more elaborate plan. New Jersey, Ohio, and Alabama maintain small permanent geological corps in the interest of the development of their mineral resources. New York, which early published systematic reports on the stratigraphy and structural geology of its territory, has since carried forward an elaborate study of its fossils, continuously maintaining therefor a small corps, and

publishing a series of paleontologic monographs, which have been of the utmost service to the geological corps of other States.

The U. S. early established the custom of attaching geologists to parties sent out for the exploration of little-known portions of its territory. Expeditions having geological inquiry for their primary purpose were instituted under Featherstonehaugh in 1834, Owen in 1839, Burt and Hubbard in 1845, Owen in 1847, Jackson in 1847, and Foster and Whitney in 1848. The work under Owen and Foster and Whitney should perhaps be classed as surveying rather than reconnaissance. In 1867 Ferdinand V. Hayden, who had previously been connected with exploratory parties, was authorized to make a geological survey of Nebraska, and his work was afterward continued in other Territories. In the same year provision was made for the survey of a belt of country, including the 40th parallel, under the direction of Clarence King. In 1871 John W. Powell, who had previously explored the Colorado cañons under Government authority, was authorized to begin the geological survey of a tract bordering the river, and this work also was continued. In the same year explorations under the direction of Lieut. George M. Wheeler assumed the character of a topographical and geological survey. In 1879 the U. S. Geological Survey was created, being made to replace the Hayden, Powell, and Wheeler surveys. Two years later its field of operations, which had originally included only the Territories, was enlarged so as to comprise the entire republic, and its corps was gradually enlarged until it came to be the most important of all governmental organizations for the prosecution of geological investigation.

Great Britain was the first European country to establish a geological survey, De la Beche being placed in charge of the work in 1832. Austria and Spain followed her example in 1849, and works of this character are now in progress in nearly all the countries of Europe as well as in the British colonies. The first reports of the surveys of New Brunswick and Newfoundland were published in 1839, and the official survey of Canada, which is (1895) still in progress, was begun in 1842.

Geological surveying, or the work of a geological corps, consists primarily in the preparation of maps showing the horizontal distribution of the various formations, and of sections showing their vertical arrangement. The facts exhibited by maps and sections are called respectively the areal geology and structural geology. For their compilation it is necessary that the rocks be classified, and the study of the formations for the purpose of classification involves the determination of their position and other physical characters, and also the determination of the fossils they contain. In extensive geological surveys it has been found advantageous to differentiate the work, employing specialists for the chemical analysis of rocks, for their petrographic determination, and for the study of fossils. In regions not previously provided with topographic maps on which to delineate the outcrops of the formations, the geological corps has performed topographical as well as geological work, and in large organizations the topographical work also is performed by a special corps. In Great Britain and most of the countries of continental Europe topographical map-work was well advanced before geological mapping was begun, and the geological corps have no topographical divisions. In the U. S. the State surveys have, as a rule, executed little or no topographic work, but have made use of such maps, usually inaccurate, as happened to be available. The national survey prepares its own topographical base-maps, employing for that purpose a large corps of engineers.

G. K. GILBERT.

Survival of the Fittest: See EVOLUTION (*Struggle for Existence*).

Survivorship: (1) the state of outliving another. Whether A outlives B is, as a rule, an easily determined question of fact. If they are the victims of a common disaster, however, no evidence as to survivorship may be obtainable. In such a case the Roman law, and some modern codes founded upon it, establish presumptions for its determination, which are based upon the assumption that survivorship depends upon the comparative physical strength of the victims. For example, if a father and son perish, the father is presumed to survive, if the son is under puberty, while if the latter is above that age he is presumed to survive. (See 4 Burge, *Colonial and Foreign Laws*, ch. 1, § 1; Code Civil, Des Successions, §§ 720-722; Code of La., §§ 936-939; Code

of Civ. Proc. of Cal., § 1963.) English law recognizes an artificial presumption on this subject. It will not balance "probabilities either that there was a survivor or who it was. We may guess, or imagine, or fancy, but the law of England requires evidence," and evidence which goes beyond that of the sexes, the relative ages and physical power of the persons who are victims of a common disaster. In the absence of other evidence than the above, the fact of survivorship is deemed unascertainable, and property rights are disposed of as if death occurred at the same time. *Newell vs. Nichols*, 75 New York 78; *Ehle's Estate*, 73 Wis. 445.

(2) The devolution of rights or obligations upon the survivor by the death of a joint owner or a joint obligor. The survivorship of rights is often termed *jus accrescendi*. "Because the right upon the death of one joint tenant accumulates and increases to the survivor." Such a doctrine was favored by the common law, for the reason that it tended to prevent a division of tenures, and to secure the continuance of the feudal system. It was not favored in equity, and was repudiated by mercantile law. Modern statutes have almost abolished it. This branch of the topic is discussed in the articles JOINT AND SEVERAL, JOINT OWNERSHIP, and PARTNERSHIP.

FRANCIS M. BURDICK.

Sus: See SUIDÆ.

Susa [= Lat. = Gr. *τὰ Σούσα*]: capital of the ancient kingdom of Elam, and afterward one of the residences of the kings of Persia; in lat. 32° N., lon. 48° E. It was taken by Assurbanipal (668-626 B. C.), and, as appears from Ezra iv. 9, 10, some of its inhabitants were sent to live in Palestine. When Alexander took the city, 331 B. C., he found great treasures of gold. Susa is the scene of several interesting biblical narratives: (1) The vision of Daniel (viii. 2); (2) Nehemiah's office as cupbearer to the king (i. 2, ii. 1); (3) the feast of Xerxes (Esther i. 2). One of the buildings at the place is revered by the natives as the tomb of Jonah. The site, which is marked by ruins, was excavated for the Louvre by Marcel A. Dieulafoy, 1884-86, who was aided in the work by his wife. (Cf. Jane Dieulafoy, *La Perse, la Chaldée et la Susiane* (Paris, 1887); Jane Dieulafoy, *À Susa. Journal des Fouilles 1884-86* (Paris, 1888); Marcel A. Dieulafoy, *L'Acropole de Susa d'après les Fouilles exécutées en 1884, 1885, 1886*, etc. (Paris, 1890-92); B. T. A. Everett, *New Light on the Bible and the Holy Land* (London, 1892, pp. 220-257).) The ruins are in the form of three large mounds. In one of these Dieulafoy excavated the palace which was built by Darius Hystaspes (521-485 B. C.), damaged by fire in the reign of Artaxerxes Longimanus (465-424), and restored by Artaxerxes Mnemon (405-362). The art treasures brought thence to the Louvre are most remarkable. Specially noteworthy are the capitals of the columns, the procession of the "immortals" (raised figures in enamel, of various colors, on the surface of the brick-work), and the figures of lions (also in enamel).

D. G. LYON.

Susa, or Sous: town of Northern Africa: 70 miles S. S. E. of Tunis; is surrounded with olive-groves, and has an extensive trade in oil and manufactures of woolen fabrics. Pop. estimated at 12,000, of whom 2,000 are Europeans and 2,000 Jews.

M. W. H.

Susan's na, History of: a short book, considered by the Roman Catholic Church to be canonical, and regarded as the thirteenth chapter of Daniel, but put among the Apocrypha in the English Bible. It relates the attempt on the virtue of Susanna, a beautiful Jewish matron, her false accusation, her final rescue from death, and the overthrow, by the judgment of young Daniel, of the wicked men who designed her ruin. It is probably a fiction of neo-Hebrew origin.

Revised by S. M. JACKSON.

Susemihl, soo'ze-mēl, FRANZ: Greek scholar; b. at Laage, Mecklenburg-Schwerin, Germany, Dec. 10, 1826; studied in Leipzig and Berlin; private docent at Greifswald 1852; Professor of Classical Philology at the same university since 1856. His works chiefly relate to Plato and Aristotle. Among them are *Genetische Entwickelung der Platonischen Philosophie* (2 vols., 1860); *Aristotle's Poetics*, with translation and notes (2d ed. 1874); text editions of the *Politics* and *Nicomachean Ethics*. In 1891 he published his profoundly learned *Geschichte der griechischen Literatur in der Alexandrinerzeit* (2 vols.), the standard work on the subject.

ALFRED GUDEMAN.

Suso, or Seuse, HEINRICH (otherwise known as St. Amadus and Heinrich von Berg): mystic; b. at Ueberlingen, in the present grand duchy of Baden, 8 miles N. of Constance,

June 23, 1220. His father was a rough soldier of the name of Jean Berg, but after his mother's death in his eighteenth year he took her name, Simon or Simeon. He studied first at Compiègne, then at Cologne, and became a Dominican monk at Compiègne 1260. He was greatly influenced by Eckhart. At first his religious life was in the dark, and he lived for several years a life of seclusion and the severest asceticism; but coming into the light, realizing as he believed with the Eternal Wisdom, he resorted in the newly found way and peace and became then an illustrious preacher, and wrote several religious works of a mystical character, which made a deep impression, and of which the chief is *Book of the Seven Wreaths* (*Horologium Sapientie Alberti*), which was partly translated into English at Douay, 1560. It is in the Dominican monastery at Ulm, Jan. 25, 1566. His collected works were translated into new High German by M. Dispenhirsch (Regensburg, 1822; 4th ed. 1864); but his writings have not as much interest as those of the other German mystics—Eckhart, Tauler, etc. F. H. S. DeWille has published selections in his *Das geistliche Leben* (Grita, 1878), 3d ed. 1879; also his works, 1878, seq.). For Simeon's biography, see his collected works, also his autobiography, *The Life of Blessed Henry Simon by Himself*, translated from the German by T. P. Knox (London, 1893); also F. Bayan, *Tristis Amici de Deo* (Lausanne, 1866), and T. Jaeger (Düsseldorf, 1866). Revised by S. M. Jackson.

Suspension Bridge (TOWN): See NIAGARA FALLS (CITY).

Suspension Bridges: See BRIDGES.

Susquehanna: borough: Susquehanna co., Pa.; on the Susquehanna river and the N. Y., Lake Erie and W. Railroad; 32 miles S. E. of Binghamton, N. Y., 59 miles N. of Carlisle (for location, see map of Pennsylvania, ref. 2-1). It is a manufacturing place, with steam-boat factory, chemical works, and locomotive and railway-car shops, and contains a public library, 2 national banks with combined capital of \$150,000, a private bank, and a daily, a tri-weekly, and a weekly paper. Pop. (1890) 3,467; (1896) 3,265.

Susquehanna River: a river formed by the union of its western and eastern branches at Northumberland, Pa. The western branch, the larger, rises in Otsego Lake, Otsego co., N. Y., at an elevation of about 1,300 feet. The western branch rises in Cambria co., Pa., and has a very tortuous and generally eastward course through a region abounding in timber and coal, but less celebrated for its fertility and beauty than the valley of the eastern branch, a portion of which, called the Wyoming valley, is renowned for the historic events of which it has been the scene, as well as for the mineral wealth which it contains. The main Susquehanna flows through a wide, open, exceedingly fertile, and very picturesque country of Devonian slates and limestones. It reaches the head of Chesapeake Bay at Fort Deposit, Md. It is a wide and stately stream, but is shallow, and is nowhere navigable to any extent, save in the spring, when the freshets bring down great rafts of logs and lumber and some loaded boats. The length of the main stream is 150 miles, of the western branch 200 miles, of the eastern (or northern) branch 220 miles. The branches afford great water-power. Canals have been built along the main stream and both branches, but have been rendered useless to a great extent by railways. Revised by ISRAEL C. ROSS-ELL.

SURREY: county of England; S. of Surrey and bordering on the English Channel. Area, 1,465 sq. miles. It is intersected from E. to W. by a range of low hills called the South Downs, consisting of chalk covered with fine turf and affording excellent pasturage, where the celebrated breed of sheep called the Southdowns is reared. To the N. of the range are extensive woods; to the S. the ground is wholly under tillage, and large crops of wheat, barley, beans, turnips, and hops are raised, and hogs, fowls, and rabbits are reared. Pop. (1891) 530,442.

SURREY: See SUMNER.

Sutcliffe, MATTHEW, LL. D., dignitary and author; b. in Devonshire about 1550; entered Trinity College, Cambridge; took holy orders, and became archdeacon of Taunton in 1576, dean of Exeter in 1598, and prebend of Wells in 1592. He founded a college at Chelsea, of which he was the first provost, the fellows of which were to devote themselves to writing the annals of their times and to combating popery and Paganism; but the institution fell into decay, became an asylum for invalid soldiers, and finally a part of Chelsea Hospital. He wrote many polemical works, chiefly

against Bellarmine and Robert Persons, among which are *A Treatise of Ecclesiastical Discipline* (London, 1604); *Disputation de Probatione* (1601); *De Caliditate et Invaliditate Christi. Breviter* (1602); *De Pontificis Romanis, et quibus Indulgentiis in Ecclesia dispensantur* (1599); *De Paganismo* (1600); *De Vera Christi Religione* (1597); *De Missa papistica* (1601); *The Unlawfulness of a Mass-sacrifice*, &c. in 1600. Revised by S. M. JACKSON.

Sutech: an Egyptian deity, usually regarded as the equivalent of Set (q. v.). He was adopted by the Hyksos (q. v.) as their special divinity, and afterward, apparently, was introduced into the East. It is somewhat doubtful whether the identification of Set and Sutech is justification in the earlier times, since as late as the eighteenth dynasty the name of Set appears as the principal part of the royal name of Seti (q. v.), which would scarcely have happened if the identification of Set with the foreign Sutech were then stamped or generally recognized. At a later period both Set and Sutech are regarded as identical, and as foreign gods as well as gods of foreigners. CHASLES R. GILLIARD.

Sutherland: a northern county of Scotland, bounded W. and N. by the Atlantic Ocean, E. by Caithness, and S. by the North Sea; area, 9,028 sq. miles, only 3 per cent. of which is under cultivation. The surface is elevated, mountainous, and rugged, especially toward the N. W., interspersed with large tracts of moorland or covered with extensive forests, where herds of red deer roam wild. Herring and salmon, and salmon, and herring fishing are the principal occupations. Pop. (1891) 21,596. Chief towns: Dunrobin (pop. 1891) 513. Sutherlandshire sends one member to Parliament.

Sutlej [Sansk. *Satadra*, or the "hundred-channelled," the *Sardara* of Ptolemy and *Satdra* or *Hasidra* of Piny]; the most eastern and southern of the "five rivers" of the Panjab, British India, and the one which receives the other four before it joins the Indus. It rises in Western Tibet, not far W. of the sources of the Hindukush and S. of those of the Indus proper, and takes a course first W., breaking through the Himalayas, thence S. W. to the Indus in lat. 29° N. The Tibetan valley of its upper course is highly picturesque and contains many hot springs. After passing the mountains it traverses the arid plains of Southern Panjab, where its waters are much used for irrigation. It has no large southern affluents. On the N. the Rias enters at the turn in its course, and 50 miles from the Indus it is joined by the mountain stream, Chibul, and Bavi, from which junction to its mouth it is called the Panjab. Its lower course is shifting. The annual floods occur in June, July, and August, and its volume of water is nearly equal to that of the Indus. Length about 970 miles, but the flow is intermittent from Hakra Tal, a lake 40 miles below its source. Boats of 40 tons burden ascend to Prosper, 970 miles from the mouth. MARK W. HARRINGTON.

Sutra, in Pali *Sutta* [Sansk. *sūtra*, a thread or string; deriv. of *year*, *sow*]; in Sanskrit literature, a short rule or aphorism, or a string of such aphorisms. Sūtras constitute an important part of Hindu literature, including all the ritual, grammatical, metrical, and philosophical works. They consist of brief sentences to be committed to memory, and were usually written separately on dried palm-leaves tied together by a string, whence the name. One of the three "baskets" or "collections" of the Buddhist Tripitaka is composed of sūtras, which profess to be the very words of the Buddha. Each sūtra or string of aphorisms begins with the words, "Thus have I heard."

Suttee (from Sansk. *sūt*, faithful wife, liter., female of *sūta*—pres. partic. of *sū*, he, being, existing, real, true, faithful); the voluntary burning of a widow on the funeral pile of her husband, a practice formerly prevalent among Hindus in India. In the event of the husband dying in a distant land, the widow would place her sandals on her breast and end herself alive into a fire. The practice is said to have been unknown to the primitive Aryans, but it is authorized by several passages in the *Puranas* (see *Cotterbrooke's Digest of Hindu Law*), although the custom is not sanctioned by the laws of Manu. For some time the custom was permitted in India under British rule, and between the years 1815 and 1826 more than 7,000 cases of suttee were reported in the province of Bengal alone. In 1829 suttee was suppressed by the British Government in India, and in 1847 the prohibition was extended to all native states under the protection of the Government. T. C. BRADSHAW.

Sutter, JOHN AUGUSTUS: pioneer; b. at Katern, Baden, Feb. 15, 1803, of Swiss parentage; was educated at the military college at Berne; entered the French service as an officer of the Swiss guard and served, 1823-24, through the Spanish campaign; emigrated to the U. S. 1834; carried on a trade with Indians and trappers at Santa Fé; crossed the Rocky Mountains 1838; traded in a vessel along the Pacific coast; founded 1839 a settlement on the site of Sacramento; received a grant of land from the Mexican Government, and was appointed governor of the northern frontier country; encouraged the annexation of California to the U. S.; was a delegate to the convention to form a State constitution; and after the admission of California as a State was elected first alcalde of his district. In Feb., 1848, gold was discovered on his estate in Coloma, his lands were invaded by gold-diggers, and the claim he had filed for 33 sq. leagues was decided against him on appeal to the Supreme Court. Being reduced to poverty, he was pensioned by the State Legislature; in 1873 removed to Litiz, Lancaster co., Pa. D. in Washington, D. C., June 17, 1880.

Sutter Creek: town; Amador co., Cal.; on Sutter creek; 4 miles N. W. of Jackson, the county-seat, 45 miles E. S. E. of Sacramento (for location, see map of California, ref. 6-D). It is in a gold-mining and agricultural region, and has a weekly newspaper. Pop. (1880) 1,324; (1890) 1,351.

Sutton: village; Brome co., Quebec, Canada; on the Canadian Pacific Railway, near the U. S. boundary (for location, see map of Quebec, ref. 6-C). Near the village is Sutton Mountain, over 1,000 feet high, the slopes of which are covered with magnificent maple groves. It is the center of the maple-sugar export trade. Pop. of parish (1891), 3,362.

Sutton: town (incorporated in 1714); Worcester co., Mass.; on the N. Y., N. H. and Hart. Railroad; 9 miles S. of Worcester (for location of county, see map of Massachusetts, ref. 3-G). It contains the villages of Sutton, West Sutton, South Sutton, Mauchaug, Wilkinsonville, Pleasant Valley, Woodbury, and Marbleville; has 5 churches, high school, 15 public schools, public library, and assessed valuation of \$1,296,578; and is principally engaged in agriculture and the manufacture of cotton goods. Pop. (1880) 3,105; (1890) 3,180.

Suture [from Lat. *sutūra*, seam, deriv. of *su'ere*, *su'tum*, sew; Eng. *sew*]: in anatomy, the line of union of two bones between which there is no motion. Where motion is intended, the union is a joint or diarthrosis. The general term for an immovable joint is synarthrosis; this includes the suture (*sutūra*), or linear articulation; the schindylesis, in which a thin lamina of bone is received between two laminae of another bone; and the gomphosis, in which a long process is inserted into a socket. A serrated suture is one between bones whose edges have projections and indentations fitting into each other; a squamous suture is between bones whose edges overlap. In surgery, suture is either the uniting of the edges of a wound by means of stitches, or it is one such stitch. The most common materials for sutures are prepared catgut, silk, and silver wire.

Suwa'row, or Suvo'roff, ALEXEI VASILIEVITCH: soldier; b. in Moscow, Nov. 24, 1729; entered early the Russian army, and was made a colonel after the battle of Kunersdorf, 1759, and a general in 1783, after the campaign against the Lezhians on the Kuban. In the second Turkish war he defeated the Turks in several important battles, and in 1790 captured the fortress of Ismail. In 1794 he commanded in Poland, and took Praga Sept. 24, 1794, after which Catherine II. made him field-marshal. His most brilliant exploit was his Italian campaign in 1799. He had fallen into disgrace under Paul I., and had even been deprived of his rank, but on the demand of the Emperor of Austria he was, nevertheless, made commander-in-chief of the Russian army which was sent to Italy to co-operate with the Austrians against France. He defeated the French on the Trebbia and at Novi, and then crossed the Alps to join Korsakoff and the Austrians under Hotz. Both the generals had been defeated, however, and Suwarow was compelled to retreat. Shortly after the Russian-Austrian alliance was dissolved, and the Russian army withdrawn from the theater of war. He died a few days after his return to St. Petersburg, May 18, 1800. His *Autobiography*, written in French, was edited by Glinka in 2 vols. (Moscow, 1819). See biographies by Polevoi (1853) and Spalding (1890). F. M. COLBY.

Svarabhakti [Sansk., vowel-fragment; *svara*-, tone, vowel + *bhakti*-, division, deriv. of *bhaj*-, to allot, divide]: a tech-

nical term of Indian grammar (*Prātiśākhya*) applied to a subsidiary vowel-sound inserted between *r* or *l* and a following consonant. This term has been adopted into modern grammar to denote the vowel appearing in the various familiar forms of anaptyxis with *r* or *l*; as in Lat. *familia* for **famlia*; *saeculum* for *saecum*: O. H. Germ. *miluh* to *melchan*, to milk; Eng. *elm* for *elm*. B. L. W.

Sveaborg: See SWEABORG.

Svend: See SWEYN.

Sven Tröst: pseudonym of SNOILSKY (*q. v.*).

Svĕtlá, KAROLINA (pseudonym of JOHANA MUŽÁKOVÁ, wife of Prof. Peter Mužák, of Prague): a Czech writer of novels of considerable fame; b. at Prague, Feb. 24, 1836. She published in 1858 her first novel, *Double Awakening*, in the Czech almanac *Máj*, and continued to enrich Bohemian literature with some fifty novels and tales. Her material is mostly drawn from the popular life and the modern society of her native country; her popular types, framed after French models, are very delicate and artistic. She also wrote many essays on education and literature, and memoirs which are widely read. Among her best novels are *Láska k básníkovi, román z časů novějších* (Poet's Love, Novel of the Present Time, Prague, 1860); *První Češka* (Prague, 1861; also published in the collection of novels *Slovanské besedy*); *Vesnický román* (The Village Romance, 1869); *Frantína* (1870); *Kříž a potoka* (The Cross near the Brook, 1871); *The Atheist* (1873). Karolina Světlá is, besides Eliška Krásnohorská (pseudonym for Henriette Pech), the author of the cycle of epic songs *To the Slavic South*, the foremost woman representative of modern Czech literature. Many of her novels have been translated into Russian, German, Polish, and French. HERMANN SCHOENFELD.

Svir: a river in the government of Olonetz, Russia. It issues from the southwestern extremity of Lake Onega, and enters, after a course of 130 miles, the eastern part of Lake Ladoga. It is navigable throughout its whole course, and forms part of the great system of rivers and canals which connects the Baltic with the Caspian and White Sea.

Swabia, or Suabia (Germ. *Schwaben*, Mod. Lat. *Sue'via*): a former territory of Southwestern Germany, corresponding nearly to the present Würtemberg and Baden, and bounded S. and W. by the Rhine, which separated it from Switzerland and France, and N. and E. by the Palatinate, Franconia, and Bavaria. Its original name was *Alemannia*, but when, in 496, the Alemanni were conquered by Clovis, the country received the name of Swabia after the Suevi, who inhabited large parts of it. In 1080 the Emperor Henry IV. made it a duchy, and bestowed it as an hereditary fief on Frederick of Hohenstaufen. Under this family Swabia prospered and became the seat of a flourishing civilization; but when the family became extinct with Conradin, who, as the head of the Ghibelline party, was executed at Naples in 1268, Swabia was broken up into many small dominions and free cities. From 1563 to 1806 Swabia was one of the ten circles into which the German empire was divided.

Revised by M. W. HARRINGTON.

Swain, GEORGE FILLMORE, B. S.: civil engineer and educator; b. in San Francisco, Cal., Mar. 2, 1857; graduated at the Massachusetts Institute of Technology in 1877, and then spent three years in study in Germany. Since 1883 he has been Professor of Civil Engineering in the Massachusetts Institute of Technology, and has also served as expert on the tenth census and as engineer of the railway commission of Massachusetts. He is the author of valuable articles in technical journals, of papers on the water-power of the U. S. in the *Reports of the Tenth Census*, and of discussions in the *Reports of the Massachusetts Railroad Commission*.

MANSFIELD MERRINAN.

Swainson, WILLIAM: naturalist; b. in Liverpool, Oct. 8, 1789; served in the commissary department of the British army 1807-15; accompanied the German naturalist Köster in his travels in South America 1815, after which he settled in London, and began in 1820 the issue of his works on natural history. In 1841 he emigrated to New Zealand, where he was attorney-general, and subsequently published several works on the natural history and social and political condition of that colony and Tasmania. Among his works are *Zoological Illustrations* (1st series, with 318 colored plates, 1820-23; 2d series, with 136 plates, 1829-33); *Exotic Conchology* (1821-22; new ed., 1841); *The Naturalist's Guide for Collecting and Preserving all Subjects of Natural History and Botany, particularly Shells* (1840); 11 vols. on zoology.

etc., in Lardner's *Cabinet Cyclopaedia* (1834-40); *Birds of Western Africa and The Natural Arrangement and History of Flycatchers* (in Jardine's *Naturalist's Library*, 1837-38); *Ornithological Drawings*, of birds from Brazil and Mexico (1834-41); *Observations on the Climate of New Zealand* (1840). He assisted Sir John Richardson in the ornithological portion of *Fauna Boreali-Americana*. Few of his day knew more about birds and no one excelled him as a delineator of them. D. in New Zealand in 1855.

Swallow [O. Eng. *swalewe*, *swealwe*; O. H. Germ. *swalawa* (> Mod. Germ. *schealbe*); Icel. *swala*]; any bird belonging to the family *Hirundinidae*, distinguished by the wide deep gape, allusion to which is evidently conveyed in the name. They have the neck rather short; the head full; the bill short, but comparatively broad and depressed; the gape very deep, and continued backward nearly as far as, or quite under, the eyes. There are no distinct rictal bristles; the wings are very long and pointed, and have only nine primaries, of which the second is generally longest, but the first is nearly or quite equal to it; the tail is forked or emarginated, and normally consists of twelve feathers; the legs are weak and small, the toes are long and slender, and with the normal number of joints; the claws curved and acute, but slender. The anatomical features demonstrate the close relationship of the family with the ordinary singing birds (such as the sparrows, thrushes, etc.), and the great differences from the swifts, which resemble them so much as formerly to have been generally united with them. There are over 125 species, and representatives are found in almost every land and every zone save the extreme polar regions. The several genera have been differentiated into two sub-families—*Hirundininae*, in which the outer edge of the wing is smooth-feathered, containing almost all of the species; and *Psittidoproceninae*, in which it is serrated or armed with stiff recurved hooks, represented by the African genus *Psittidoprocne* and the American *Stelgidopteryx*. The species are among the most active and graceful of birds, and their circling and sweeping flight is well known to observers. They feed almost exclusively on insects, which they take on the wing. Their mode of nesting is various (for the nest of the barn-swallow, see NESTS OF BIRDS), the eggs five or six. The most common North American species are the purple martin (*Progne subis*); the cliff-swallow (*Petrochelidon lunifrons*); the barn-swallow (*Chelidon erythrogaster*); and the bank-swallow or sand-martin (*Cotyle riparia*). The so-called chimney-swallow is a swift. See SWIFT and MARTIN.

Revised by F. A. LUCAS.

Swamp'scott: town; Essex co., Mass.; on Massachusetts Bay, and the Boston and Maine Railroad; 2 miles N. E. of Lynn, and 13 miles N. E. of Boston (for location, see map of Massachusetts, ref. 1-1). It is a noted watering-place with an excellent beach and large accommodations for season and transient guests; contains the villages of Swampscott, Beach Bluff, Phillips Beach, and Mountain Park; and has a high school, 14 district schools, public library, 3 hotels, and 5 churches. In 1894 the assessed valuation was \$5,000,000. Pop. (1880) 2,500; (1890) 3,198.

Swan [O. Eng. *swan*; O. H. Germ. *swan* (> Mod. Germ. *schwan*); Icel. *svanr*]; any one of those swimming birds of the family *Anatidae*, sub-family *Cygninae*, which have a bill nearly equally broad throughout and as long as the head; the cere soft and extending to the eye; neck long and slender, consisting of twenty-two to twenty-six vertebrae; the front toes with a large web; the hind toe without a lobe; the tail short and rounded; the second and third wing-quills the longest. They are the largest species of the family, and among the largest of birds. Some authorities place all swans in one genus, *Cygnus*; others admit four genera, *Cygnus*, *Olor*, *Chenopsis*, and *Sthenelus*. Omitting the Coscoroba swan (*Coscoroba coscoroba*), which probably belongs with the ducks, there are nine species, all but two inhabitants of the northern hemisphere. The exceptions are the black-necked swan (*Sthenelus melancorypha*) of Chili and the black swan (*Chenopsis atrata*) of Australia. The North American swans, whistling swan (*Olor columbianus*) and trumpeter swan (*O. buccinator*), are fine birds, both white. The tame swans are of two European species—red-billed swan (*Cygnus olor*) and Polish swan (*C. immutabilis*). The former is found in a wild state throughout a great part of Europe, while comparatively little is known of the second species, some authors considering it to be a mere variety of the first. *Cygnus immutabilis* is so named from the fact that the young—or cygnets—are white, while those of other species are gray. Though once

held in considerable esteem for the table, domestic swans are now bred merely for ornament.

F. A. LUCAS.

Swan, JAMES: soldier and author; b. in Fifeshire, Scotland, in 1754; went to Massachusetts at an early age; was a clerk in Boston; published a *Dissuasion to Great Britain and the Colonies from the Slave Trade to Africa* (1772); became captain of artillery, secretary to the Massachusetts board of war, member of the Legislature in 1778, and afterward adjutant-general of the State. In 1787 he went to Paris; wrote *Causes qui sont opposées au Progrès du Commerce entre la France et les États-Unis de l'Amérique* (1790); acquired a large fortune; returned to the U. S. in 1795; returned to Europe in 1798; in 1815, upon the suit of a German with whom he had transactions, he was arrested and thrown into a prison in Paris, where he remained fifteen years. He also published *On the Fisheries* (1784); *Fisheries of Massachusetts* (1786); *National Arithmetick* (1786); and an *Address on Agriculture, Manufactures, and Commerce* (1817). D. in Paris, Mar. 18, 1831.

Swan-pan: See ABACUS.

Swan'sea (Welsh, *Abertawe*): seaport in Glamorganshire, South Wales; at the mouth of the Tawe; 216 miles W. of London (see map of England, ref. 12-E). Owing to the rich coal-fields in the vicinity, and its position on a bay affording safe anchorage, Swansea has developed into one of the most important manufacturing towns in Great Britain. Nearly half the entire exports are tin-plates, the rest being coal, coke, iron, steel, zinc, copper, alkali, etc. The imports include copper, zinc, lead, silver, tin, iron, and their ores; also sulphur, grain, timber, etc. The total tonnage of vessels entered and cleared in 1893, exclusive of that coastwise, was 1,320,144. The parliamentary borough returns two members. Pop. of municipal borough (1894) 95,399.

Swansea: town (incorporated in 1668); Bristol co., Mass.; on Mt. Hope Bay, and the N. Y., N. H. and Hart. Railroad; 4 miles N. W. of Fall River (for location, see map of Massachusetts, ref. 5-1). It contains the villages of Swansea, North Swansea, South Swansea, Center Swansea, and Hortonville; has ten public schools, a public library, and a Protestant Episcopal church; and is principally engaged in agriculture and in bleaching and dyeing. Pop. (1880) 1,355; (1890) 1,456.

Swanton: town; Franklin co., Vt.; on the Missisquoi river, near the north end of Lake Champlain, and on the Cent. Vt. and St. Johns and Lake Cham. railways; 9 miles N. of St. Albans, the county-seat (for location, see map of Vermont, ref. 2-B). It contains a union public school, a national bank with capital of \$50,000, a weekly paper, quarries of white and variegated marble, and spring-bed and other factories. Pop. (1880) 3,079; (1890) 3,231.

Swarga, or **Svarga** [Sansk.]: in Hindu mythology, the heaven over which Indra presides. It is the residence of beatified mortals and of the inferior gods, and is supposed to be situated on Mt. Meru. See INDRA and MERU.

Swarthmore College: a coeducational institution at Swarthmore, Delaware co., Pa., opened in 1869. It was founded by the Society of Friends belonging to the Yearly Meetings of Philadelphia, New York, and Baltimore, for the purpose of furnishing opportunities for higher education to its own members and to persons of other denominations. Women as well as men are members of its faculty and of the board of managers. It offers four courses of study—arts, letters, science, and engineering—for the completion of each of which a separate degree is given. In 1894 it had twenty instructors, 185 students, and 15,800 volumes in its library. The presidents have been Edward Parrish, Edward H. Magill, William Hyde Appleton, and Charles De Garmo. Besides the main college building, in which are the dormitories, libraries, the biological laboratory and museum, and class-rooms for the departments of ancient and modern languages, mathematics, history, and economics, there is a spacious science building containing the chemical laboratory, the physical laboratory for teaching electrical engineering, the draughting-room, and shops of the engineering department. There is also an astronomical observatory and two gymnasiums, one for the young men and one for the young women.

CHARLES DE GARMO.

Swatow: a port of China, opened to foreign trade by the treaty made at Tientsin in 1858. It is situated on the north or left bank of the river Han, about 5 miles within its mouth, in the province of Kwangtung but near the borders of Fuh-kien; lat. 23° 20' 43" N., lon. 116° 39' E. (see map

of China, ref. 8-J). It is the shipping-port of the city of Ch'ao-chow-foo, 35 miles inland, and of San-ho-pa, 40 miles farther up the Han. The site of the native town is but little raised above the level of the river, which is here about a mile wide. The southern bank, on which the foreign settlement is located, is bold, and lined with hills of an average height of 400 to 500 feet. The foreign community is small. The natives, who in both features and language resemble the people of Fuh-kien rather than those of Kwangtung, are noted for their turbulence and their hostility to foreigners. Their dialect, which is unintelligible to natives of Canton, approximates closely to that of Amoy. Sugar-making is the great industry of the neighborhood. The trade of Swatow, which is considerable, is mostly in the hands of natives, and is chiefly with Hongkong (180 miles distant), Shanghai, and Niuchwang. In 1893 917 vessels, with a tonnage of 883,695 tons, entered, and the same number cleared. The net foreign imports for that year amounted to 8,238,721 Haikwan or custom-house taels, and the net native imports to 9,512,749 taels. Of the foreign goods imported, 7,486,902 taels came from Hongkong, 383,617 taels from Cochin-China, Tonquin, and Annam, 96,975 taels from Russia, and 40,320 taels from the U. S. The chief imports were opium, value 2,888,740 taels; rice, 3,473,247 taels; bean-cake (used for manure in the sugar-plantations), 253,786 taels; raw cotton, cotton and woolen goods, metals, matches, and kerosene oil. The exports included tea (about 7,000 piculs), sugar (valued at 3,125,009 taels), grass-cloth, liquid indigo, prepared tobacco, joss-sticks, and joss-paper, and amounted to 6,445,682 taels, or about \$676,966 U. S. gold. In the same year 93,095 native passengers left the port, but only 56,217 entered. More than half of the native emigration, for which the port is noted, is directed to the Straits Settlements. Pop. 22,500.

R. LILLEY.

Swayne, JOHN WAGER: soldier and lawyer; son of Noah H. Swayne; b. at Columbus, O., Nov. 10, 1834; graduated at Yale College in 1856; studied law and practiced at Columbus; major of the Forty-third Ohio Volunteers 1861; became colonel; served through the Atlanta campaign; lost a leg at Salkahatchie, S. C.; breveted brigadier-general U. S. Vols. Feb. 5, 1865, promoted brigadier-general Mar. 8, 1865, and major-general June 20, 1865; mustered out of the volunteer service Sept. 1, 1867. He was a commissioner of the Freedmen's Bureau in Alabama, where he commanded the U. S. forces and administered the reconstruction acts; retired July 1, 1870. In 1880 he removed to New York.

Swayne, NOAH HAYNES, LL. D.: jurist; b. in Culpeper co., Va., Dec. 7, 1804; was clerk in an apothecary's shop in Alexandria; studied law; was admitted to the bar in 1823, and began practice at Coshocton, O.; in 1826-29 was prosecuting attorney of Coshocton County; in 1829 was elected to the State Legislature; removed to Columbus, O.; was U. S. district attorney 1831-41; was chosen judge of the court of common pleas in 1833, but declined the office; was again elected to the Legislature in 1836, and was prominent in organizing asylums and institutions for the deaf and dumb, the blind, and the insane; joined the Republican party on its formation; in 1861 was appointed a justice of the U. S. Supreme Court; resigned 1881. D. in New York, June 8, 1884.

Swaziland: See SOUTH AFRICAN REPUBLIC.

Sweaborg, or Sveaborg, svä-ää-borg: a fortress of Russia, on the northern coast of the Gulf of Finland (see map of Russia, ref. 5-C). The place was originally fortified by Sweden. When Finland became a province of Russia (1809), the latter made it a military and naval dépôt. The isle of Vargoe is the central or principal fortress: the isle of Great Oester-Svartoe the principal naval dépôt and dockyard. See HELSINGFORS.

Sweat, or Perspiration [*sweat* is deriv. of *sweat* (verb) < M. Eng. *sweten* < O. Eng. *swētan*, deriv. of *swāt*, sweat; O. H. Germ. *swēiz* (> Mod. Germ. *schweiss*): Icel. *svið*; cf. Lat. *suda're*, to sweat; Gr. *ὑψω*, sweat; Sanskr. *svid-*, to sweat]: the fluid exuded through the pores of the skin, consisting of water with numerous solids in solution. The amount of water excreted from the skin either in the form of the insensible perspiration, which maintains its softness and moisture, or in perceptible sweat, is but little less than the volume of the urine or the equivalent in water of the moisture exhaled from the lungs in breathing. It varies with the seasons and climate, sweat being most profuse in summer and the warmer regions. The action of the skin is complementary to that of the kidneys, chilling of the integu-

ment producing renal hyperæmia. The amount of solid excretory matter and carbonic acid gas eliminated by the skin is small, but can not be suppressed without danger to life.

Experiments of closing the pores by a coating of varnish or tin-foil, both in man and lower animals, have induced alarming depression and death. Conversely, the artificial stimulation of the perspiration is a valuable channel for eliminating morbid matter in impaired health or disease. Bathing, friction, and clean clothing, by favoring activity of the sweat-glands and open pores, are means of preserving health. The sweat is secreted by the sudoriparous or sweat-glands, coiled tubular masses beneath the skin, with excretory tubules terminating on the surface. (See HISTOLOGY, *The Skin and its Appendages*.) The tube is about $\frac{1}{16}$ th of an inch in diameter, the coils or glands vary from $\frac{1}{16}$ th to $\frac{1}{4}$ th of an inch in diameter. The number of sweat-openings varies on different surfaces; thus, as enumerated by Krause, the palm of the hand (see figure) has 2,736 to the square inch, the back of the hand 1,490, sole of the foot 2,685, top of the foot 924, forehead 1,258, cheek 548. The number of sweat-glands in the body is estimated at 381,248, and the aggregate length of tubules as 24 miles.

Surface of the palm of the hand: a portion of the skin about half an inch square, magnified four diameters (Sappey): 1, 1, 1, 1, openings of the sweat-ducts; 2, 2, 2, 2, grooves between the papillae of the skin.

Revised by W. PEPPER.

Sweating Sickness: one of the prevalent and fatal epidemics which occurred during the fifteenth, sixteenth, and early part of the seventeenth centuries. It was also known as pestilent sweat and as the English ephemera, as the English people both at home and abroad were chiefly attacked. In Germany, Holland, Sweden, and Denmark it prevailed more mildly. It first appeared in England in 1485. It was of brief period, both in individual cases and in duration of single epidemics. Fully half of the population in infected towns had the disease, and the mortality was great, but where death did not result all danger was past in twenty-four or forty-eight hours, and epidemics rarely lasted a month. The other great English epidemics were in 1506, 1517, 1528, and 1551. In the last two the disease for the first time left English soil, appearing in various parts of Western Europe. After 1551 no further epidemics were met with till the beginning of the eighteenth century, since which numerous outbreaks of the disease, now generally known as *miliary fever*, have occurred. Miliary fever is of common occurrence to the present day, scarcely a year passing without an epidemic in some part of the world; but it is mild in character and very rarely spreads to any considerable distance. The attack consisted of a febrile and sweating period. It began with pains in the back, shoulders, and limbs, flushes of heat, oppression at the liver and stomach, pain in the head, delirium, palpitation, followed by heaviness and desire to sleep, which in fatal cases tended to become profound coma or stupor. Profuse sweating then set in, in favorable cases leading to speedy convalescence. Often there was an eruption in the skin, which afterward desquamated in cases which recovered. The patient was liable to one or many relapses. The disease spared the aged and young, attacking chiefly middle-aged, plethoric men of all classes and of every rank. Both in England and on the Continent the greater prevalence of this disease among Englishmen was attributed to their peculiarly gluttonous, excessive diet. By Hecker, Guy, and others the several epidemics of this disease are ascribed to preceding periods of atmospheric and telluric insalubrity, the influence of gathered armies, and to the absence of house and street drainage in the larger cities and towns. Its period of incubation, rapid progress, and speedy convalescence disconnect it from epidemics of the typhus class. The nature of sweating sickness has been the subject of much conjecture. Doubtless it is some special infection and not influenza, malaria, or rheumatism, as older writers were disposed to think. Probably various diseases have been described under this name. The treatment consists mainly in rest and tonics.

WILLIAM PEPPER.

Sweating System: In popular usage, a term applied to the practice followed in certain trades of sub-contracting for a low class of work, which is done sometimes on the premises of the laborer, sometimes on the premises of the sub-contractor, and often under unsanitary surroundings and with excessive hours of labor. This use of the term, however, is erroneous, for sub-contracting may be, and often is, practiced without the injurious results popularly associated with it. The system of sub-contracting obtains largely in iron and steel rolling, in which trades labor is as highly paid as in any others. The practice is consistent with but not inseparable from what is meant by sweating. An accurate definition of this term can not be given. The House of Lords select committee in their report accepted several, but none is satisfactory. Indeed, the chairman, Lord Derby, said later: "We endeavored . . . for some years to ascertain what meaning attached to the word 'sweating,' and we never could find any." The reason is that, while the evils which the term sweating has been selected to describe undoubtedly exist, there can properly be no such thing as a sweating system. The so-called system is characterized by the absence of system, by the lack of those very features which denote the factory system or general industrial organization. Hence it must be regarded as an excrescence, an abnormal phase of industrial development, which when properly understood may be regulated, and, so far as environment is concerned, rectified. The term "sweating" is in this connection a term of reproach, and was first applied to tailors who took home work that their wives and children might assist them. Later, as Charles Booth pointed out, they found it profitable to do all their work at home. Then they began employing others, thus becoming sweaters instead of being sweated. Among boot-makers the "sweater" is known as the "chamber" or "garret" master. Among other trades it is the sub-contractor or middleman who has been his nickname.

Extent of the Practice.—Sweating is an effect of the survival of domestic industry. Factory labor is not subject to it. One must not understand that it can exist only with domestic industry. Before the introduction of organization and protective legislation, factory employees were subject to most of the evils associated with sweating; while to-day, in much of the "house industry" of Germany, whether the workman is his own master or comes in direct relations with the employer-in-chief, there is no complaint. Sweating is common in certain trades—in Europe in tailoring, boot-making, furriery, needlework of all kinds, nail and chain making, and dock labor; in the U. S. the practice is almost exclusively confined to tailoring and other kinds of needlework, the preparation of feathers, the manufacture of cigars, artificial flowers, and fancy leather goods.

The tailoring trade is the employment in which sweating is chiefly practiced. To describe the process will be of most service. The wholesale clothier supplies the cloth, which in many cases also is cut and trimmed in his own workshops. The goods are then farmed out to contractors, for the most part Jews, to be made up and returned at a fixed price per garment. The contractor is generally the lessee of a small room, usually attached to his own lodgings in a tenement-house. In this room two or three "frames" of workers are employed—a machine-man, a baster, and a finisher constituting a "set." Wages are fixed on a piece basis. Where, for example, \$7 is allowed for making up two dozen coats, \$3 goes to the machine-man, \$2.50 to the baster, and \$1.50 to the finisher. The laborer must frequently work sixteen or eighteen hours in order to earn a nominal day's pay. The sweater works with his hirelings, overseeing them and often, doubtless, driving them to do their utmost. Sometimes his own margin of profit is so small that he is compelled to do this for protection against loss; but he is not always a pitiless taskmaster, and is besides on a footing of fair equality with his employees. Larger sweaters receive the cloth from wholesale clothiers, and cut and trim it in shops of their own, making up part of it on the premises and distributing the remainder among families working in their homes.

The essential features are as follows:

1. **Sub-contracting.**—The profits of the middleman are dependent upon the service he employs. Sub-contracting applied to unskilled or poorly skilled work makes competition painfully acute, and immediately reduces both contract and piece prices to the lowest possible minimum. Sub-contracting has developed particularly in the clothing business because the trade centers to a large extent in domestic in-

dustry, and can be pursued by women with tolerable domestic occupations, because this method enables the wholesaler to save the cost of rent and superintendence, and to hold back his capital from investment in goods till the last moment, because it permits him to meet seasonal requirements by letting a large or small number of contracts as his experience demands, and because a very few dollars is all a middleman needs to start business. There is a tendency to do away with the middleman altogether, as is shown by large houses in London establishing workshops in the East End, and by New York dealers opening shops in outlying country districts, where rentals to home-workers will be less than in the tenements.

2. **Irregularity of Employment.**—This is common to all domestic industries. Large and well-organized establishments find it cheaper to run continuously than to stop during the dull seasons. No such condition exists in the sweated trades. Coupled with this is the evil of abnormally long hours of labor, which follow partly as a consequence of the above and partly because the small master works with his employees.

3. **Low Wages.**—These are due in several causes, among which are competition among sub-contractors, remuneration made to depend upon profits, the presence of a surplus of unskilled labor in cities, and the fact that much of the work can be performed by women who are only auxiliary supporters of the family. In certain cities of the U. S. there is the additional factor of an immense immigrant population, many of them Jews, and all having a relatively low standard of existence as well as endowed with patience and subservience. It must be borne in mind that all persons working under the sweating system are not paid starvation wages. The skilled contingent commands fair remuneration. Because so much of the work is bad, and need only be so, is one reason why it is cheap. The proportion being large, the number of laborers in receipt of meager earnings is naturally also large. Failure to discern this fact has led to confused notions in reference to sweated trades. Low wages accompany inferior efficiency. The sweating system furnishes aggravated cases.

4. **Unsanitary Conditions.**—These naturally result from using the dwelling as a workshop, particularly if lodgers are taken to make up the required "set." The evil is probably augmented in cities where this class of people live in tenement-houses.

What are the remedies, and how shall they be applied?

1. The most important is reorganization of the sweated trades. The main features of such reorganization are the development of large shops, substitution of superintendents remunerated by fixed salary for middlemen contracting by the job, and trade-union organization among workers. The second feature is especially important, and will probably come about as the first one grows. Large sweat-shops, which are uncommonly severely condemned, are in reality not only better conducted than "gang-sweating" or "home-working," but are performing a useful step in the evolution of the industry from house to factory. Labor organization among unskilled and over-crowded occupations is a difficult matter, but the London dockers and the boot and shoe operatives in Massachusetts furnish evidence that it is feasible, and that much may be thereby accomplished.

2. Licensing by municipal authority, under stringent regulations as to cleanliness, use of sleeping apartments for work-rooms, employment of persons outside the family, and precautions against infectious diseases. Tagging tenement-made garments under penalty of a good-sized fine is also an effective provision.

3. Adequate inspection service for sweat-shops, large and small. Only in this way can health and morality be served.

There are no reliable statistics showing the extent to which sweating is practiced. The evils associated with the system are concomitants rather than products. Most of them are incident to lack of skill, physical inefficiency, moral weakness, and other factors which make for poverty.

E. K. L. GUNN.

Sweden [*Swedish, of Sweden; Fr. Suède (Suh'de); Germ. Schweden; Af. Swed, Swene; Lat. Suetor; O. Eng. Sæcon, Seodas*]; one of the confederated kingdoms of Sweden and Norway, comprising the eastern slope and southern end of the Scandinavian Peninsula, with Öland and Gotland islands (see map of Norway and Sweden). Area, including lakes, 172,870 sq. miles (pop. (1900) 4,794,991, or 28 per sq.

mile; (1893) 4,824,150. The most of the boundary with Norway is formed by the watershed of the Kiölen Mountains, and that with Finland by the Torneå river and its branches.

Topography.—The coast is 4,740 miles long, of which 4,100 are on the Baltic and Gulf of Bothnia, the remainder on the Cattegat and Skager Rack. The floods are few, and the adjoining seas generally shallow, with gentle slope. The coast is bordered by a narrow ribbon of islets called the *skärgård*, rocky and bare on the west coast, but green and fertile on the east. The Sound, 2½ miles wide at its narrowest part, separates Sweden from the nearest point of Denmark. The islands are most numerous about Stockholm.

The Baltic slope of the peninsula is gentler than the Atlantic one, and in Norrland (the northern part of Sweden) it descends in a series of terraces, giving its rivers alternately gentle courses, when they expand into lakes, and rapids, or cataracts. The southern part of Sweden or Gothland has a good development of rocky hills, and is separated from the central part, or Svealand (Sweden proper), by a broad low land filled with great lakes. The extreme south is ancient Skania, and is very fertile. Northern Gothland is relatively arid. Beyond Stockholm is Upland, the classic ground of Sweden, consecrated to ancient traditions. Dalecarlia, N. W. of Stockholm, and on the Norwegian frontier, is a beautiful and picturesque land with gay, hardy, and independent inhabitants; here Gustavus Vasa found the support necessary to overthrow the tyrannical Christian.

The highest mountains are in or near the Norwegian frontier, from 66° to 68° N. lat. The highest known is Kebnekaise, or Ivanstenen, in lat. 68° N.—more than 7,000 feet high. Sulitelma, 2° farther S., and long considered the highest mountain in Sweden, is 6,154 feet high. The culminating points of Norway are considerably higher. Sweden is not properly mountainous; it only descends a long and relatively gentle slope. Glaciers are very numerous in the north, covering a total area of 150 sq. miles. The largest are about Sarjektjokko (6,825 feet high, and between the two mountains above named), where on a surface of 460 sq. miles they cover 70. The glaciers are reported as growing.

Rivers and Lakes.—A score or more of rivers descend the slopes, form lakes in their course, have a length of 150 to 250 miles, and empty into the Bothnia or Baltic. The quantity of water they pour into the Bothnia keeps it almost fresh. The innumerable lakes occupy one-twelfth of the entire surface. They are generally small, but about thirty have an area of 40 sq. miles or more. The largest is the Wener, between Gothland and Svealand; area, 2,150 sq. miles; 144 feet above the sea; greatest depth, 295 feet. The second in size is Lake Wetter, a few miles S. E. of the preceding; area, 733 sq. miles; 290 feet above the sea; greatest depth, 410 feet. It is celebrated for the beauty of its shores, the clearness of its waters, its fogs, and its sudden storms. Lake Mälär, the third in size, and penetrating Stockholm, fiord-like in form, is only a few inches above the Baltic, and is divided into a series of levels but a few inches apart. It is said to have 1,200 islands.

Climate.—The climate is very mild for the latitude, and storms pass usually W. or S. The annual precipitation is from 10 to 40 inches, and is greatest on the southwest coast. It is said that the harvests are fifteen days later than in the eighteenth century.

Geology and Mineral Products.—Primitive crystalline and azoic rocks cover the most of the country, and the chief metalliferous beds are in the upper layers of these. Cambrian and Silurian rocks are not rare, and some Triassic and Cretaceous exposures are found. The Glacial period was an important one in Sweden, and has left traces everywhere. Mining is an important industry, and the production of iron is large. The chief districts are the Gellivara, within the Arctic Circle, and the Dannemora, in Upsala. In 1892 the chief mineral products were as follows: Pig iron, 478,696 tons, and bar iron, 273,510 tons (320,071 out of the total 1,291,933 tons of iron ore was exported); coal, 199,380 tons; gold, 1,907 oz.; silver, 113,430 oz.; lead, 1,760,721 lb.; copper, 1,641,598 lb. Zinc and manganese are also produced, and cobalt and nickel are found.

Fauna and Flora.—The fauna and flora must have migrated into Sweden after the Glacial period, and are more Finnish than German. The forests are very extensive, covering two-fifths of the area, and are characterized by spruces and birches to the north, pines and oaks in the center, and beeches in the south. The reindeer are nearly all domesticated, but the large pasturage area they require and their

tendency to epizootic diseases greatly limit their usefulness. The bear, wolf, lynx, and glutton are disappearing, while the fox and elk appear to be increasing, and the roe-deer is extending its range farther N. The swan is a common visitant of the lakes.

Food-fish are very abundant, and include, in fresh water, the salmon (by far the most important), the eel, pike, perch, and turbot; in salt water, the herring (by far the most important), flatfish, cod, mackerel, and sprats. The herring of the east coast are much smaller than those of the west.

Products.—The climate and soil are not very favorable for agriculture, but this is made up by the care given to the art. Only one-fifteenth of the area is cultivated; one part in ninety-two in Norrbotten, but one-third in Malmöhus. Barley and potatoes reach 68° N. lat.; rye passes N. of Haparanda, at the north end of Bothnia; wheat, formerly cultivated only S. of Stockholm, reaches the Dal river, 75 miles farther N. The farms are generally small, but they give occupation to about half of the population. The largest area is in oats, but the largest agricultural crop is potatoes. Horses are relatively numerous (one to every ten persons), due to the character of the roads. The stock generally is of poor native races, but the dairy industry is growing rapidly, as London is an accessible and profitable market.

Divisions.—The country is divided into twenty-four governments besides the city of Stockholm, as follows:

GOVERNMENTS (LÄN).	Area, square miles.	Pop. Dec. 31, 1892.
Stockholm (city).....	13	257,037
Stockholm (rural district).....	3,015	154,634
Upsala.....	2,051	122,008

Norrbottn.....	40,870	110,193
Lakes Wener, Wetter, Mälär, Hjelmar.....	3,516
Totals.....	172,876	4,824,150

Population.—The population has shown for 150 years a considerable surplus of females (1,065 to 1,000 males); it has also shown a steady growth of nearly 1 per cent. per annum. The last is in spite of a considerable emigration to America, and is due to the high birth-rate, and not to immigration, which is very small. About 10 per cent. of the births are illegitimate, due not to immorality but to thrift and narrow circumstances; the parents usually marry later. The Finns number about 17,000; Lapps, 6,500; Jews, 3,000; other foreigners, 15,000. Aside from these, the Swedish type is pure and unmixed, and the ancient division into Göta (Goths) and Svea (Swedes) has about disappeared. The Lutheran is the state church, and other religions, though tolerated, are few. Education is compulsory, schools of all grades are numerous (including two ancient and highly esteemed universities, at Upsala and Lund respectively), and the percentage of illiteracy is evanescent. Serious crimes are relatively rare, but pauperism is large and increasing.

Imports and Exports.—The value of the annual imports is about \$100,000,000, chiefly textiles, colonial wares, and coal; the annual exports are valued at \$90,000,000, chiefly timber, animals and their products, and ores. Germany is the chief importer, Great Britain the chief buyer. The merchant navy consists of about 1,500 craft of over 100 tons burden, one-third steamers. Gothenburg is the most frequented port, Stockholm next, and 22,000 vessels visit Swedish ports annually.

Railways.—The railways have a length of 5,454 miles (1894), of which 1,851 miles belong to the state. The most noteworthy railway is that which connects Stockholm and Trondhjem in Norway, and the most northern railway in

this weight is the one which extends from the head of Bothnia northward to Gällivare and beyond, and is in process of construction to Ofoten Fjord, on the Norwegian Polar Sea.

Government.—Sweden has her own constitution, and governs herself, except for foreign affairs. Her system of government is the outgrowth of centuries of history, like that of Great Britain. The king is intimated with the executive, and is aided by a council of sixteen ministers. Taxation and legislation (the latter subject in the king's veto) are entrusted to the two elective houses of a parliament, one of 148 elected members holding for nine years, the other 228 paid members holding for three years. The government of the twenty-four provinces is in the hands of prefects appointed by the king, but local affairs are administered by communal and municipal councils. The municipalities are limited to cities of over 25,000 inhabitants, and are at present Stockholm, Gottenburg, Malmö, Norrköping, and Galle. The total revenue is about \$27,000,000, collected chiefly from customs (\$10,000,000), from land taxes and state property (\$5,000,000), internal revenue (tax stamps, spirit licenses, income tax), from the post-offices, and from the profits of the national (Svenska) bank. One-third is expended on the army and navy; one-fourth only on the royal household. The public debt is \$22,000,000 (1904), contracted for state railways. The army is small, and the navy is intended only for coast defense. See ARMED SERVICES OF WAR.

History.—The early mythical history of Sweden is dignified and attractive, and the gods of the Northmen displayed their chief activity in Njardar. The Goths, who played so important a part in the downfall of the Roman empire and the reformation of Europe, seem to have come from Gothland. Authentic history begins about 1000 A.D., when Olof became a Christian. The people did not accept Christianity for 100 years, and pagan ideas and customs lingered long after. The discussions between Goths and Swedes were heated about 1000, and their amalgamation has continued since without serious interruption. The early history was terminated in 1289 by the battle of Årslöv, when Queen Margaret of Denmark and Norway, a striking historical figure, took the Swedish king Albert prisoner, and the union of the three Scandinavian countries was confirmed in 1397 by the so-called the Union of Kalmar.

Sweden was very restless under the union, and tried repeatedly to break away, but without permanent success, until led by Gustavus Vasa (1523). With this king began the brilliant period of history which made Sweden one of the first powers of Europe, gave her extensive lands to the S. and E., and made her at one time the leader and defender of Protestantism. During this period appeared his grandson, Gustavus Adolphus, one of the most brilliant figures in all history, and by far the greatest of Swedish kings, and the period ended with the resignation of his daughter Christina in 1654. Then follow 100 years of decline, during which Sweden was robbed both of her influence and her foreign possessions, until Gustavus IV. (1792-1809) proved so impotent and perverse that he was dethroned and his posterity repudiated.

Charles XIII. was then elected (1809-19), but was childless, and Marshal Bernadotte was invited to become crown prince. He accepted and founded the present line, under which Sweden's material and constitutional progress has been steady and secure.

See also SWEDEN AND NORWAY; also NORWAY AND DENMARK. See also WARD'S *Sweden and Norway* (1892) and LARSEN'S *Swedish Statistics for the World's Columbian Exposition* (1893).

MARK W. HARRINGTON.

Sweden and Norway: a federated kingdom occupying the Scandinavian Peninsula. The mainland area is 207,221 sq. miles, and the population at the beginning of 1891 was 6,285,287; Sweden has nearly three-fifths of the area and three-fourths of the population. For details, see the articles NORWAY AND SWEDEN. The federation was formed in 1814, and goes little further than allegiance to a common king and a common interest in foreign affairs. The king is Oscar II. of the house of Ptolemy Corro founded by Bernadotte. The law of succession is the same in the two countries. The common affairs are decided upon by a council of state composed of Swedes and Norwegians. The federation is not without political friction, and is less satisfactory to Norwegians than to Swedes.

MARK W. HARRINGTON.

Swedishborg, KARLSTAD: (Helsingborg) is in Stockholm, Sweden, Jan. 20, 1899. His father, Jasper Swedishborg was Bishop of Skara in West Gothland, and was charged with

the care of the Swedish churches in England and in the North American colonies. His family was connected by blood with the Swedish nobility. He was educated at Uppsala and then traveled widely through Europe. He attained to great eminence by the writings upon mathematics and mechanics, and later on the natural sciences and on history. In 1719 he was made member of the board of mines by Charles XII. He assisted the king at the siege of Frederikshall in 1719 by transporting some vessels over 14 miles of land by machines he invented.

He had always been a thoroughly religious man, but for a few years before 1745 his diaries and manuscripts (which have been published to the extent of twelve or more volumes) show that he was changing the direction of his studies from the physical and natural to the physical and spiritual. In that year, he tells us, he "was called to a new and holy office by the Lord himself, who manifested himself to him in person, and opened his eyes to a new of the spiritual world, and granted him the privilege of conversing with spirits and angels." In 1747 he resigned his office of assessor, which he had held for thirty years, requesting that half of his salary might be continued to him. The king accepted his resignation, and granted him a pension for life equal to his full salary. He wrote to a friend: "My sole view in this resignation was, that I might devote myself to that new function to which the Lord had called me. On resigning my office a higher degree of rank was offered me, but this I declined, lest it should be the occasion of inspiring me with pride." From 1749 to 1756 he published the *Arctica Caelum* in eight 4to vols.; in 1759, *An Account of the Last Judgment and the Destruction of Babylon*; in 1760, *On the White Horse mentioned in the Revelation, Heaven and Hell*; in 1761, *On the Planets in our Solar System and in the Starry Heavens*; in 1762, *On the New Jerusalem and its Heavenly Inhabitants*; in 1763, *The Doctrine of the New Jerusalem concerning our Lord, some Concerning the Sacred Scriptures, some Concerning Faith, some Concerning Life, a Continuation concerning the Last Judgment and the Destruction of Babylon*, and *Angelic Wisdom concerning the Divine Love and Wisdom*; in 1764, *Angelic Wisdom concerning the Divine Providence*; in 1766, *The Apocryphal Revelations*. He had written a much larger work, *The Apocryphal Revelations*, as far as the tenth verse of the nineteenth chapter, which he did not publish, nor, as far as is known, finish—it has been published since his death; in 1768, *The Delights of Wisdom concerning Conjugal Love*; in 1769, *A Brief Exposition of the Doctrine of the New Church*, and a small work entitled *The Intermixture between the Good and the Evil*, which is called in the English translation *A Treatise on Lust*. In 1770 he published his last work, *The True Christian Religion, containing the Universal Theology of the New Church*. He also left voluminous manuscripts, of which Dr. J. F. S. Tafel, professor and librarian in the University of Tübingen, published many. After the publication of the *True Christian Religion* he went to London, and while there, on Christmas Eve in 1771, he was struck with hemiplegia. After a few weeks he recovered his speech, and his faculties were close to the last. His strength gradually declined, and he died Mar. 29, 1772.

He has never been charged with imposture, and they who think he was insane must rest that opinion on the fact that for more than twenty-five years, with brief interruptions, he claimed that he was in the spiritual world whenever he wished to be there, and published what would fill volumes of things there seen and heard. The best edition of his works is by H. L. Tafel (10 vols. 8vo, Stockholm, 1892-70); many are published in English translation by the New Church publishing societies (e.g. New York). See his *Life*, by D. Worcester (Boston, 1883). For an abstract of his doctrines, see NEW JERUSALEM, CHURCH OF.

Swedish Green: See SCHEER'S GREEN.

Swedish Language: generally, a member of the Indo-European division of the Teutonic group of languages. With Danish it forms the minor group East Norse, as distinguished from West Norse, made up of Icelandic and the modern popular dialects of Norway. Its present territory is the kingdom of Sweden, together with neighboring parts of Russian Finland and Estonia. Chronologically, two main periods are recognized in the history of the language, viz. Old Swedish, from the end of the Viking age to the Reformation, in round numbers from 1050 to 1540; and Modern Swedish, from the Reformation to the present time.

The linguistic separation of the Scandinavian north falls within the Viking age (700-1050). Down to the year 1000, however, although local differences are visible even early in the period, the language is still, to all purposes, homogeneous, and only after the introduction of Christianity, at the middle of the eleventh century, do distinct dialects arise; namely, Swedish-Danish and Norwegian-Icelandic. The latter was not strictly differentiated until the beginning of the thirteenth century, the former not until its end. The material for the history of the earliest period of Swedish is contained in runic inscriptions, in all nearly 2,000, most of them from the eleventh and twelfth centuries. The oldest extant MS. is from the end of the thirteenth century (1281), after which time a native literature began to appear. The linguistic territory of Old Swedish comprised modern Sweden, with the exception of parts of the west which were Norwegian, and the southern provinces of Skaane, Halland, and Blekinge, which were Danish, besides, and to a greater extent than at present, coast regions of Finland, Esthonia, and Livland. The language of the period shows numerous local differences, but only in one case, the dialect of the island of Gothland, which is frequently described in contradistinction to Old Swedish as Old Gutnic, are they sharply defined. A common national language, a movement toward which is distinctly visible after 1350, gradually developed itself in the main out of the middle Swedish dialect of Södermanland.

Modern Swedish is the continuation, in direct descent, of the Old Swedish dialect of the midland provinces of Södermanland and Östergötland, which even in Old Swedish shows few local differences. Its beginning is coincident with the Reformation, and its first important literary monument is the translation of the Bible, the so-called Gustavus I. Bible of 1541. The language may be said to have assumed its present appearance early in the eighteenth century. The important external modifications from Old Swedish down were first the introduction of a multitude of Low German words into the vocabulary during the fourteenth and fifteenth centuries, principally as a consequence of commercial connection with the Hanseatic League. A Danish influence, the result of political conditions under the Danish sovereigns from the end of the fourteenth century to the beginning of the sixteenth, made itself widely felt, not only in the vocabulary by the introduction of Danish words, but in phonology and inflections. A second influx of German words came in with the Reformation. A reactionary tendency which looked toward the displacement of foreign elements and the rehabilitation of older words and forms has several times shown itself. This movement was directed at the beginning of Modern Swedish in the sixteenth century against Danicisms. In the latter half of the seventeenth century many words were introduced from Old Swedish and Old Icelandic, a process repeated in the nineteenth century by the further reinstatement of Old Swedish forms and the adoption of words from the spoken dialects.

Internally, the general tendency of the language from the fourteenth century down has been toward weaker phonetic conditions and simpler inflectional forms. At the beginning of the eighteenth century the Old Swedish system of inflections had to a great extent disappeared, and present conditions already prevailed. Some of the changes then observable date, however, from an earlier period. In the fifteenth century, for instance, falls the use of the ending *-s* for all genitives, and the displacement of the first plural of verbs by the third. In the sixteenth and seventeenth centuries all case-declension was lost in adjectives, and nominative, dative, and accusative in substantives were merged in a single form.

Swedish and Scandinavian language is distinctively characterized by the use of the suffixed definite article with substantives, and the formation of a passive voice of verbs by the addition of the reflexive pronoun, Swedish *-s*, to the corresponding active form. As an East Norse dialect it has, in common with Danish, as important characteristics the change of the diphthongs *ei*, *au*, and *ey* to the long vowels *e* and *ö*, respectively; the almost total absence of *u*-umlaut, and the passive form in *-s* (Icel. *-st*). In contradistinction, however, to Danish, which has throughout weakened the vowel of the inflectional ending to a voiceless *e*, Swedish has, in many instances, retained *a* and *o*; final *k*, *t*, *p* remain in Swedish after a vowel where they are weakened to *g*, *d*, *b* in Danish. Swedish has, in point of fact, on the whole much better preserved archaic phonetic conditions, although it has gone almost as far as Danish in

the simplification of its grammar. As in Danish, but a single case-ending, genitive *-s*, occurs with substantives; neither the strong nor the weak adjective has inflection for case. Unlike Danish, where there is throughout no distinction of person in the verbal conjugation, Swedish has a distinctive form in the second person plural, and the threefold gender of substantives has been retained.

Swedish is still spoken in a number of dialects, some of which, like forms in Dalecarlia and the island of Gothland, notably deviate from the literary language. Generically, they may be arranged in a northern, middle, southern, and Gothland group. The northern or Norrland group includes, besides North Swedish proper, the dialects of Finland and Esthonia. The southern group is spoken in language territory once Danish, to which it is morphologically akin. Middle Swedish, out of which the literary language proceeded, shows the least dialectic differentiation, and now, as always, most nearly approximates the literary form.

For the pronunciation of Swedish, see Henry Sweet, *A Handbook of Phonetics* (Oxford, 1877). An exhaustive scientific treatment of the older language is contained in the chapter by Adolf Noreen, *Geschichte der nordischen Sprachen*, in Paul's *Grundriss der Germanischen Philologie* (vol. i., Strassburg, 1891); E. C. Otté, *A Simplified Grammar of the Swedish Language* (London, 1884). See also S. E. Rydquist, *Svenska språkets lagar* (4 vols., Stockholm, 1850-70), an historical grammar of the Swedish language, in Swedish.

WILLIAM H. CARPENTER.

Swedish Literature: the literature of the Swedish people.

Heathen Age.—Although few fragments remain, it may be assumed that Sweden produced various literary works before the introduction of Christianity. The laws, which were given a written form in the following period, were composed much earlier, several runic inscriptions and figures, notably those of *Röksten* and *Ramsundsborg*, point to poetical works similar in character to the poetry of Iceland-Norway, and finally in the preface to *Þidreks saga* a *Bern* reference is made to the existence of a great body of lays in Denmark and Sweden.

Medieval Period.—The influence of Christianity on the literature of Sweden made itself felt even later than on that of Denmark. Not until the middle of the thirteenth century did any Christian writings appear, but from that time great activity was displayed in the cloisters. The earliest theological writer of importance is Magister Matthias (d. about 1350), canon of Linköping and St. Birgitta's teacher, who is supposed to have made the first translation, or rather paraphrase, of a portion of the Old Testament (before 1340). During this century and the two following centuries other books, both of the Old and the New Testament, were put into Swedish. (See G. E. Klemming, *Svenska Medeltidens Bibeldarbeten* 1848-55.) Matthias was also the author of commentaries on the Bible, originally written in Latin but afterward translated into Swedish. The only other religious prose work from this period that deserves special mention is *Heliga Birgittas Uppenbarelser* (The Revelations of St. Birgitta), "the first Swedish work that entered into the world's literature." (See BIRGITTA, SAINT.) It is full of warmth and originality and abounds in bold images. Of far greater importance is the influence exerted by Birgitta throughout the North, both on religion and literature. In the cloisters of her order a great mass of native writings was preserved and produced. The efforts of her followers were directed mainly toward translating continental mystical writings into Swedish. She encouraged the use of the Swedish language in the pulpit, and consequently a great mass of sermons, both in Danish and Swedish, must have been produced during this period, comparatively few of which, however, have been preserved. Of these only one, the Danish *Postille*, was printed before the Reformation. For specimens of Swedish sermons, see Klemming's *Svenska Medeltids-Postillor* (1879).

Swedish literature is remarkably rich, as compared with Danish, in legendary compositions. The most important collections are the so-called *Fornsvenskt Legendarium*, a translation of the *Legenda aurea* of Jacobus de Voragine, made shortly after the appearance of the original, but preserved in a MS. from 1350 (ed. by George Stephens, 1847-74), and *Vitas Patrium*, in a MS. from 1385 (ed. by Klemming). Somewhat similar in character to these legends are the collections of miracles, of which a great number existed, both in Denmark and Sweden. Here may also be mentioned the

romances *Barbaris och Joseph* and *Siu sin valdare* (The Swartt Wierd Man). These last two and many other medieval prose works are contained in Klemming's *Prosalitter från Medeltiden* (1892).

Of secular prose literature the most important work is *Den Ryske Kungens af Håfslings* (Concerning the Government of Kings and Princes), ed. with Latin translation and notes, Copenhagen, 1668), an adaptation in part of Egidius Romanus's *De Regimine principum*, written about the middle of the fourteenth century. See K. F. Söderwall, *Anteckn. öfver Kungens-Rysken* (1896).

In historical writings Sweden must yield the palm to Denmark. The earliest prose history is the *Chronica Gothorum* (1470) of Erikus Olai (d. 1496), a dry sound writing, like all the works of this class, in Latin, but later translated into Swedish. Of far greater interest are the rhymed chronicles in which Sweden anticipated her sister kingdom of Denmark by a century. The oldest of these is the *Krikoberättelse*, which treats of the strife between King Birger and his brothers Erik and Waldemar. It is undoubtedly the work of one who lived at the time the events described occurred. These close with the year 1382. Others are *Nya Krönika* and *Lilla Riksräkning*, all written in Swedish. See Klemming's *Swenska Medeltidens Rikshistorier* (1866-69).

In addition to the *Raflesia* (see DAYTON LITERATURE), Swedish translations of a number of other romantic works exist from the Middle Ages. The first of these, following shortly after the *Raflesia* (see *ibid.*), is *Abraham*, made in 1390 under the direction of Dr. Jonsson (Grip from the Latin prose tale *Historia de Præfata*). All have been edited by Klemming.

The principal original poetical production of this period in Swedish is found in the popular ballads (*Folklåtar*). It may be assumed that at least some of them were composed as early as the twelfth or thirteenth century in Denmark or Saxon models, and from there carried into Sweden. The later development of the ballads is practically the same in Sweden as in Denmark. The best collections of Swedish ballads are Oeljer and Afzelius's *Swenska Folklåtar* (2 vols., 1814-16). Later edition by Bergström and Höjer (1889) and A. L. Arwidsson's *Nordiska Färdslåtar* (2 vols., 1814-42).

The oldest Swedish works in the vernacular are the provincial laws, which are derived in their original form from the heathen period, although they were not reduced to writing until much later. (See SCULPTURE). The earliest of these and the oldest Swedish MS. in existence is the *Västgötalag*, codified at the beginning of the thirteenth century, and preserved in a MS. from the end of that century. Besides the provincial there were also town laws, guild laws, and court laws.

From the Reformation to 1640.—Although the new doctrines were officially introduced into Sweden at the parliament of Vesterås (1527), they met with much opposition from all classes, and were not finally accepted by the people until 1593. Their influence upon the literature, however, was immediate and far-reaching. As in Denmark, this showed itself in the beginning chiefly in theology. In 1526 the New Testament was translated into Swedish by Laurentius Andreeus (1482-1552), the earliest leader in the movement, and in 1540-41 the whole Bible was given a native dress under the direction and largely by the actual labor of Laurentius Petri (1499-1573). Olaf Petri (1497-1572), a brother of Laurentius, rendered good service to the language as well as to religion by *Den första psaltaren* (A Short Sermon) and *Den svenska massan* (The Swedish Mass, 1531), the foundation of the present Swedish Church service. He is the author of the first Swedish hymnal, *Några gudhelige Wisor, utdragne af den Heliga Skrifft* (1530), which was followed by two other collections, partly original, partly translated from the German. His brother also composed a number of hymns; with these exceptions the period is extremely bare in religious poetry. A similar poverty is shown in secular poetry, the only works of any importance being the rhymed chronicles, of which may be mentioned the later edition of *Lilla riksräkning* (1529), Daniel Hansson Hufv's (d. 1611) *Könung Ericus den XIV:s Krönika*, etc., and Karl IX's *Riksräkning*. The separation from Denmark and the triumph of Gustavus Vasa served to arouse the national enthusiasm, which found expression in numerous histories and chronicles, both in Latin and the vernacular. Olaf Petri's *Swenska krönika* is the first attempt to bring into discredit the claims of earlier writers for the antiquity of Swedish history. Although extremely uncritical, it may be

regarded as the precursor of later historical methods. Its effects, however, were not immediately apparent, and Johannes Magnus (1490-1544) in his *Historia de omnibus Gotharum Sueonumque Regibus* (Helsing, 1644) traces the royal line back to the Flood. The most prominent historian is Johan Messenius (1579 or 1581 to 1667), author of *Swenske illustrata* (14 vols., written in Latin verse and prose). Minor historians are Peder Sparf (d. 1602), Erik Tegel (d. 1606), Agnitus Gise (about 1599-1639), and Axel Oxenstierna (d. 1624). The only prominent name in the first half of the seventeenth century is that of Johan Hare, or Huron (1628-1652), the founder of the study of northern antiquities in Sweden. His influence upon the following period, especially through his connection with Stjernhjelm, was very great.

The only known specimen of dramatic literature in Sweden before the seventeenth century is a translation of the Latin *De omni peccatoris, qui peccaverit morietur*. The earliest original school-drama presented is *Johans Comedien* (1590), attributed to Olafus Petri (ed. by Mandersström, Stockholm, 1849). This was followed by a number of others, all in the vernacular, the subjects being taken from the Old Testament. The best of these is *Hatfjerris och Juditha Comedien*, by an unknown author. Gradually the original didactic element gives place to the æsthetic, the subjects being taken from profane history and from legends. A still further advance is marked by the treatment of national history. In this latter respect the Swedish drama is in strong contrast to the Danish, which with one exception shows no choice of national subjects until the middle of the eighteenth century. The earliest profane drama is *En festligh Comedien vid namn Tribe* (A Merry Comedy by the Name of Tribe), probably by Magnus Olaf Astorplörens (d. 1647), produced in 1610 (ed. by P. Kihlström, Upsala, 1892). In this play the moralizing of the school drama is for the first time wholly absent. The most original dramatic author of the period is Johan Momenius. He planned to represent Swedish history in fifty plays, only six of which were completed. The first of these, *Isac* (1611), marks the beginning of the Swedish national drama. The national character of the plays is increased by the introduction of ballads, many of them original with the author, and the representation of peasant types (ed., with the exception of *Gustavus I.*, by H. Schölk, Upsala, 1896-98; see also G. Ljunggren, *Johans Momenius som dramatisk författare*, Nord. Univ. Föreläs., 1902). Andreas Johannis Prytz (1596-1655) wrote two religious historical plays, *Oluf Skuttlung* (1630) and *Comedien om konung Gustaf I.* (1631), which display considerable satirical power. The school-dramas continued to be written and performed until the end of the seventeenth century.

Period of Sovereignty (Stormakt), 1640-1719.—The political brilliancy of Sweden during the seventeenth century was reflected in education, literature, and science. Gustavus Adolphus was not only a great soldier and statesman, he was also a patron of letters and a writer of decided ability. Through his efforts elementary and high schools and gymnasia were established, the University of Upsala was given new dignity and importance, and the intellectual formation of the Reformation was replaced by a real culture. His example was nobly followed by his successors, Queen Christina, Charles XI, and Charles XII. The University of Lund was founded (1628), several scientific institutions were established, foreign scholars, among others Descartes and Hugo Grotius, were invited to Sweden, and many of the leading men of the country both encouraged learning and made contributions of their own. As a result of the newly acquired national pride, great interest was displayed in history, especially that of Sweden, but with the exception of Oluf Rudbeck, the principal historical writers of this period were foreigners—Chemnitz, Puffendorf, and others. Attention was also directed toward the study of archaeology, linguistics, and similar subjects. Olaf Verelius (1615-82) translated many of the Icelandic sagas, and Johan Peringskiöld (1654-1726) translated the *Heimskringla*. The investigation of Sweden's legal system was begun in this period under the direction of Johan Sparfvech (1596-1675), called the father of Swedish jurisprudence. Philosophy was almost wholly under the influence of Descartes, but Bishop Anders Rydellius (1671-1709), the first great Swedish philosopher, displays considerable originality. In anatomy and botany Rudbeck made many important discoveries. Urian Hjärne (1641-1734) did good service in attacking the superstitions of his time, especially the belief in witchcraft. The great mystic Eusebius Swensonius (q. v.) was in early

life distinguished for his studies in mathematics and mineralogy. The most marked feature of the literary and scientific production of this period is originality.

The interval between 1640 and 1740 is often called the Stjernhjelm period, partly from the fact that Georg Stjernhjelm (1598-1672) was its greatest poet, but far more because the influences introduced by him continued to prevail long after his death. He has with sufficient accuracy been called the father of Swedish poetry; he might more properly be called the creator of modern Swedish literary expression, for it is due chiefly to his efforts that Swedish has become the most melodious of the Scandinavian tongues. It was not until after he had reached middle life that Stjernhjelm discovered his poetical genius in the long didactic poem *Herkules*. Filled with an enthusiasm for classic literature and his native tongue, he introduced his countrymen to the teachings of the Renaissance and showed them how this foreign element could be welded with the national language and character. He was the first in Sweden to make use of the hexameter, the alexandrine, the sonnet, the epigram, and the humorous lyric. The latter, in the hands of Bellman, was destined to become one of the distinguishing marks of modern Swedish poetry. His successors, while continuing his efforts to refine and expand the language, contributed but little of real poetic worth. Among them may be mentioned Samuel Columbus (1642-79), a pupil of Stjernhjelm, called the Swedish Flaccus from his *Odis Sue-thicæ*; Peter Lagerlöf (1648-99), author of a number of graceful songs and hymns; Johan Runius (1679-1713), whose collection of poems *Dudaim* was the most popular of his time; and Lasse Johansson (circa 1640-74), called from his pseudonym *Lucidor* *den olycklige*. By the side of this classical school appears a pseudo-romantic, largely influenced by the second Silesian school and by the later Italian poets, which sought to oppose the formalism of Stjernhjelm's successors. In spite of this, however, the poetry of its first prominent representative, Gustaf Rosenhane (1619-84), owes its value to the form rather than to the content. He resembles Stjernhjelm, furthermore, in his warm love of country and in his attempts to introduce new verse-forms, among others the French variety of the sonnet. Gunno Eurlius Dahlstjerna (1658-1709) was possessed of far greater originality, but his talents were hampered by their foreign influence. He also introduced a new verse form, the *ottava rima* with Alexandrines, exemplified in his principal poem *Kungaskald* (The King's Skald). The best hymnists of this period are Håkon Spegel (1645-1714), called the Wallin of the seventeenth century, and Jesper Svedberg (1653-1735). The most interesting prose work of that period is Rudbeck's *Atlantica*.

Period of Freedom, 1719-72.—In this period the activity of the preceding time was continued; a number of academies and learned societies were founded, the royal theater was opened, and scientific investigation was carried still further. Among the many scientists were the naturalist Karl von Linné (1707-78), the chemists Torbern Olof Bergman (1735-84) and Karl Vilhelm Scheele (1742-86), the physicist Anders Celsius (d. 1744), and the medical writer Nils Rosén von Rosenstein (1706-73), called the father of Swedish medical science. The most prominent linguist was Johan Ihre (1707-80).

The prevailing foreign influence during this period was the French. This was due to many causes, but its advance was hastened by the marriage of Louisa Ulrika, sister of Frederick the Great, to the Swedish king Adolphus Frederick III. The French influence made itself felt not only on the literature, but also on the whole culture of the period. The dominating figure is Olof von Dalin (1708-63), after whom the latter part of it, from 1740, is frequently named. In spite of his French prejudices Dalin rendered a real service to Swedish prose through the publication of *Den Svenska Argus* (1732-34), modeled on *The Spectator*, the first serious attempt at periodical literature in Sweden. His poetical productiveness was forced by the requirements of his position as court poet. Of Dalin's contemporaries may be mentioned Karl Gustaf Tessin (1695-1770), Anders Johan von Höpken (1712-89), both famous for their eloquence; Jakob Henrik Mörk (1714-63), author of the first Swedish novel, *Adalrik och Göthilda*; Jakob Wallenberg (1746-78), whose *Min son på galejan* (My Son on the Galeley) is influenced by Swift and Holberg; Karl Gyllenborg (1679-1746), author of the first modern Swedish comedy; Fru Hedvig Charlotta Nordenflycht (1718-83), who received the title of the Swedish Sappho. Of special interest as illus-

trating the taste of this period is Gustaf Philip Creutz (1731-85), whose pastoral *Atis och Camilla* was for a long time the most popular Swedish poem. Belonging as much to the following period as to this is Karl Mikael Bellman (1740-95), the first great humorous poet of Sweden. In his treatment of subjects he stood entirely alone, and the moral undertone of his apparently reckless songs fell on deaf ears. His genius did not receive full recognition until after his death, when the frivolous spirit of the French school had given place to the earnestness of the romanticists. He is the only Swedish poet of the eighteenth century who enjoys general popularity.

Gustavian Period, 1772-1809.—The pseudo-classic style continued to be cultivated. The Swedish Academy, founded in 1786, was a French Academy in miniature, while the national theater, revived by the king, was as conventional as the Théâtre Français. Opposed to this French movement was a group of writers who sought to develop the national spirit. The leading spirit among the academicians was Johan Henrik Kellgren (1751-95), poet and critic, who deserves the title of the literary dictator of his time. His literary criticisms were published in *Stockholmsposten*, of which he was editor from 1788. After Kellgren's death his place was taken by Karl Gustaf af Leopold (1756-1829), who had the misfortune to outlive his time. He excelled in didactic poetry, his *Predikaren* (The Preacher) being his most popular effort in this direction. Among other poets of this group are Johan Gabriel Oxenstjerna (1750-1818), who translated *Paradise Lost*, and Anna Maria Lenngren (1755-1817), the foremost Swedish poetess. In opposition to the Academy and the principle it represents are Thorild, Bellman, Bengt Lidner (1757-93), a poet of feeling, and Karl August Ehrensvärd (1745-1800). The Finnish poet Frans Mikael Franzén (1772-1847) belongs in part to this period.

1809-30.—After the revolution of 1809 and the restoration of the freedom of the press, the revolt against the academic school took definite shape, and went to the furthest extreme of romanticism. The first leaders in the movement were the two young poets Per Daniel Atterbom (1790-1835) and Vilhelm Fredrik Palmblad (1788-1852), who in 1807 formed a literary society called *Auroraförbundet*, among the other members of which were Samuel Johan Hedborn (1783-1849), P. A. Söndén (d. 1837), and Karl Fredrik Dahlgren (1791-1844). The main principles of this society were those of the new romantic school in Germany. In philosophy they followed blindly the system of Schelling. Their literary discussions and original works were published in the periodicals *Polyfem* (Stockholm, 1809-12) and *Phosphorus* (Upsala, 1810-13), from the latter of which they were called Phosphorists. In spite of the many absurd features of their poetry and criticisms, the Phosphorists rendered a real service to Swedish literature by preparing the way for a sounder conception of the nature of poetry. Their faults are those of their German models. The discussion between the Academy and the Phosphorists was conducted with fierceness and brutality. The leading disputants were Per Adam Wallmark (d. 1858), the representative of the Academy, and the members of the Aurora Society already mentioned. The discussion continued until about 1825. In many respects it resembles the contemporary Baggesen-Oehlenschläger feud. (See DANISH LITERATURE.) In opposition to the Phosphorists, though also representing a romantic movement, are Göterna (The Goths), who sought inspiration in the culture of their Scandinavian ancestors. They differed from the Phosphorists, too, in avoiding a quarrel with the Academy. The representatives of the school formed a society in 1811 called *Götiska förbundet*, with *Iduna* (1811-24) as its organ. Among the charter members were Jakob Adlerbeth (d. 1844), Erik Gustaf Geijer (1783-1847), and Leonard Fredrik Rååf (1786-1872). The most valuable service rendered by the society was in arousing public interest in early Scandinavian literature and culture, especially through the publication by Geijer and Arvid August Afzelius (1785-1871) of the first collection of Swedish ballads. The absurd side of the movement is displayed in the epics and tragedies of Per Henrik Ling (1776-1839). Standing apart, as its name implies, is still another school, Neutrer (Neutrals), who represented the principles of Goethe, Schiller, and Herder. Its organ was *Lycæum*, and its leading writers were Johan Olof Wallin (1779-1839), the greatest Swedish hymnist, Franzén, and Benjamin Högjer (1767-1812).

Esais Tegnér (1782-1846), the Swedish Oehlenschläger, is sometimes regarded as a Goth, sometimes as a Neutral. In reality he was neither. For the exquisite form of his prose

and even he is indebted to his academic training; in his love for the Northern poet he resembles the Greek in the early edict of his genius he is a Northerner, in the last scene of the world. Of one thing only was he indignant. His clear, logical mind could not endure the obscurity of the Platonists, and he opposed them fiercely as long as they continued to assert themselves as an independent school. Again, more by the example of his writings than by the force of his arguments, succeeded in establishing modern Swedish poetry on a firm basis, and through his *Frithiofs Saga* his name was carried beyond the bounds of the North. The three epic poets Erik Johan Stagnelius (1738-1803), Erik Axel Wallin (1791-1829), and Karl August Nordin (1789-1825), though at first influenced by the Platonists, accepted an independent position.

NARRATIVE.—The field of literary parties having ceased, Swedish literature began a more powerful development, which has been continuous. The most distinguished writers by the beginning were Karl Jonas Ludvig Adolph (1798-1868), author of poems, plays, novels, and critical essays; the Finn Johan Ludvig Runeberg (1804-77), whose poetry is characterized by a healthy realism; Karl Vilhelm Böttger (1803-79), poet, translator, and biographer; Bernhard Elze Malinström (1810-62), poet and critic. Of later writers may be mentioned the poets Karl Vilhelm August Strandberg (Tala Qualla 1818-77), Gunnar Wennerberg (b. 1817), an imitator of Bellman, and Oskar Patrick Sturzenbecker (Örvar Dill, 1811-69), who was also a critic. Of the Swedish novelists of the nineteenth century the most popular is undoubtedly Fredrika Bremer (1801-65), at one time almost as much read in the U. S. as in Sweden. Other novelists are Magnus Jakob Cronquist (1795-1865), Karl Anton Wetterberg (Örvar Adam, b. 1804), Emilie Carlen (1807-192), Karl Fredrik Hildebrandt (1807-50), Zacharias Topelius (b. 1816), and Maria Sofia Schwart (1819-94). Of the newest authors may be mentioned Viktor Rydberg (b. 1829), the leading living Swedish prose-writer, Karl Johan Gustaf Sjöström, the most original living Swedish poet, and Karl David af Wirsén (b. 1842), an aesthetician. The leading realist is August Strindberg (b. 1849), the Swedish Zola.

SWIFT, HENRY: philologist; b. in 1845; graduated at Oxford in 1870. He has edited a number of Old English texts for the Early English Text Society; *King Alfred's West Saxon Version of Gregory's Pastoral Care* (1871-75); *King Alfred's Orosius* (1880); *The Literal Glossary* (1885), etc.; has published *A History of English Sounds* (1874, 2d ed., 1886); *A Handbook of Phonetics* (1877); *New English Grammar, Spoken English*, etc., an original and very ingenious system of shorthand, *Current Shorthand, Orthography and Phonetics* (1882); and several readers and primers of Anglo-Saxon, Middle English, and Icelandic. He received honours Ph. D. from Heidelberg. H. A. Rams.

SWIFT, JOHN EASON: inventor, mechanic, and engineer; b. at Pampsey, Cheshire, en., N. Y., Oct. 21, 1862. After working at carpentry and joinery for a time, he practiced

mechanism until 1891, when he gave his attention to the designing of machinery. In 1893 he became the manager of the workshop of the mechanical arts department of Sibley College, Cornell University, and remained there until 1899. Amongst his best designs are the "straight-line engine," and hot bulb, with the aid of his pupils in the Sibley College shops, the first engine of that type, which has as its characteristic feature a straight-line frame, provisions for the reduction of engine friction, and a simple and efficient governor. He has written for the technical journals, principally for *The American Machinist*. He is a past president of the American Society of Mechanical Engineers.

H. U. Ferguson.

Sweet Bay: See BAY.

Sweetbread: the pancreas of *Trachurus* (pp. 67) of an animal, used as food. The former is usually called stomach-sweetbread and the latter throat-sweetbread.

Sweetbrier: See KILARYN.

Sweet-flag: See *AMARIS CALLITA*.

Sweet-gale: See GALE.

Sweet-gum: See GUM-ROSE.

Sweet Potato: a trailing vine (*Ipomoea batatas*, formerly called *Batatas edulis*) of the morning-glory family, producing large thickened edible roots. The plant is widely cultivated for food in the tropics and the warmer portions of temperate countries. Its native country is unknown, but the evidence points strongly to an American origin. Its aboriginal American name was *tuberos*, whence comes the word *potato*, later applied to the Irish or round potato (*Solanum tuberosum*). The sweet potato is a staple crop in the southern parts of the U. S. where it thrives in the sandy or loam soils. It is propagated by suckers or sprouts which spring from the tubers. It very rarely flowers. There are many diseases of the sweet potato, for an account of which the reader should consult the bulletins of the New Jersey experiment station. *Plt's Sweet Potato Culture* is the only guided manual devoted to the plant in the U. S.

L. H. Bailey.

Sweet-sap: the soft, sweet, and aromatic fruit of a small tree, the *Annona squamosa* of tropical America, indigenous not only in Brazil and the West Indies, but also in Hindustan and the East Indies. The fruit is greenish and resembles an artichoke in size, in form, and in the scaly covering. The pulp is soft, somewhat fleshy, sweet, and mucous, though with a musky, aromatic odor and flavor. It is extensively used as an article of food, and it has proved the staff of life to the people of Hindustan, in seasons of famine. Its seeds have an acrid, perhaps a poisonous, quality, shared by the leaves, which have also a disagreeable smell. In India it is called mustard-apple, though the true mustard-apple is *A. reticulata*.

Revised by L. H. Bailey.

Sweet Springs (formerly Rameyville); city; Saline co., Mo.; on the Blackwater river, and the Mo. Pac. Railway; 24 miles N. W. of Sedalia (for location, see map of Missouri, ref. 3-E). It is the center of an agricultural and stock-raising region, and contains several sweet medicinal springs, 2 State banks with combined capital of \$125,000, and a weekly newspaper. Pop. (1880) 1,152; (1890) 1,187.

SWENSON, CARL AARNE, Ph. D.; clergyman; b. at Sugar Grove, Pa., June 25, 1857; educated at Augustana College and Theological Seminary, Illinois; pastor of the Swedish Lutheran church at Lindsborg, Kan., since 1879, and founder (1881) and president of Bethany College at the same place. He was a member of the Kansas Legislature (1888-90), and has been editor of several Swedish journals. In 1885 he was elected English secretary, and in 1890 president of the General Council. H. K. J.

Sweyn, wæn, Swegen, or Svend: King of Denmark and father of Canute the Great; invaded England to avenge the massacre of the Danes by the English in 1002, and ravaged a great part of the country. In 1014 he made another invasion and this time reduced the Anglo-Saxon kingdom, forcing Ethelred to flee. He proclaimed himself king, but died (1014) before he had fully established his power, leaving Canute as his successor. P. M. C.

SWIFT: a common name for the birds of the family *Myiropodidae* (or *Cypselidae*), probably first bestowed on the European species from its rapid flight. In external appearance the swifts much resemble the swallows, but the bill is decidedly smaller, and the tail is not soaly, but simply covered with skin. The primaries are ten in number, the

first and second being of equal length; the tail is variable in shape, deeply forked in some, almost square in others, but always composed of ten feathers. The first toe is directed more or less forward, and in the more typical swifts (*Cypselinae*) the second, third, and fourth digits have but three joints each, owing to a fusion of the basal phalanges. Anatomically the swifts are very different from the swallows, and do not belong to the same order. There are about fifty species distributed over the greater portion of the globe; with the exception of the East Indian tree-swifts (*Macropteryx*), which are prettily clad, they are mostly of somber plumage. They are insect-eaters and pass the greater portion of their time on the wing, and some, like the chimney-swift or chimney-swallow (*Chaetura pelagica*) of the U. S., even gather the materials for their nests in full flight. They build in caves, crevices of the rock, nooks of old buildings, hollow trees, or adapt themselves to civilization in chimneys, while an African swift suspends its nest to the fronds of a palm. The nests are gummed together with saliva, and the famous edible birds'-nests, built by the little swifts of the genus *Collocalia*, consist entirely of a peculiar salivary secretion. The eggs are white, two in number in many species, four or five in others, while the tree-swifts (*Macropteryx*) lay but one egg. One species of typical swift (*Micropus melanoleucus*) is found in the western parts of the U. S., while the common chimney-swift abounds in the Eastern States. The common species of Europe (*Micropus apus*) ranges from Great Britain to India, occurring also in Northern Africa. The swifts are usually divided into two sub-families, according to the number of phalanges, but the tree-swifts (*Macropteryx*) are by their numerous peculiarities entitled to rank as a separate family (*Macropterygidae*). In the western parts of the U. S. the name swift is applied to a small fox (*Vulpes velox*), and in the southern parts to a small lizard (*Sceloporus undulatus*). F. A. LUCAS.

Swift, JONATHAN: satirist and divine; b. in Dublin, Ireland, Nov. 30, 1667. He was the posthumous son of Jonathan Swift, an Irish official, and of his wife Abigail Erick, of Leicester. Of his birth in Dublin, the dean remarked in after-life, "I happened by a perfect accident to be born here, and thus I am a Teague, or an Irishman, or what people please," but his descent was purely English. He was kidnaped, as an infant, by his nurse, who carried him to Whitehaven, in Cumberland, where he remained nearly three years, when his mother took him away to Leicester. At the age of six he went to Kilkenny School, and on Apr. 24, 1682, entered Trinity College, Dublin. He was an idle scholar, often censured, and in 1688, on his twenty-first birthday, he quitted the university in disgrace. He went to his mother at Leicester, and was presently glad to accept the position of amanuensis in the family of his eminent kinsman, Sir William Temple, at Moor Park. There Swift remained, with two intermissions, until Temple's death in 1699. His health was bad, and after a surfeit of golden pippins in 1689, he began to suffer from the mysterious complaint of his lifetime, which, as is now conjectured, must have been a labyrinthine vertigo. In 1692 he received the degree of M. A. from Oxford, and to the same date belong his earliest existing compositions, his awkward and prosaic *Pindaric Odes*. In 1694 he left Temple and returned to Ireland; early in 1695 he took priests' orders and the small Ulster living of Kilroot. The solitude weighed upon him, and in the spring of 1696 he went back to Temple's service. In 1696 he began *A Tale of a Tub*, and in 1697 he wrote *The Battle of the Books*, which was first published in a joint volume in 1704, although prepared for the press in 1698. At the death of his patron Swift applied to William III., whose favorable attention he had attracted, but the petition failed to reach the king. He therefore was glad to accept the post of secretary to Lord Berkeley, but was dismissed in Dublin. In Feb., 1700, the living of Laracor, to which were presently appended two other small incumbencies and a prebend, secured for him a scanty competence. He was now invited by an old flame, Miss Waring, "Varina," to marry her, but he refused to do so in a strangely violent letter. He was more interested in "Stella," Sir William Temple's orphan ward, Esther Johnson; in 1701 she and her friend Mrs. Dingley came over to Ireland to be near Swift. When he was absent from Dublin, and his visits to England were frequent and lengthy, these ladies occupied his chambers. In 1701 Swift made his first appearance as an author, by the publication of the anonymous pamphlet *Contests and Dissensions in Athens and Rome*.

This was successful, and the *Tale of a Tub* volume, in 1704, raised a storm of notoriety, but Swift took little part as yet in literary or political life. In 1708 he became suddenly a great power in the Whig party, and published a succession of vigorous and brilliant tracts. These, and other anonymous publications in prose and verse, were collected in a volume of *Miscellanies* in 1711, in which *Baucis and Philemon*, written in 1706, and the *City Shower* are to be found. Meanwhile Swift had risen to the highest level of London society. In 1705 Addison had addressed him as "the most agreeable companion, the truest friend, and the greatest genius of his age," and Swift was accepted on these terms by most of the leading wits and statesmen of the court of Anne. His influence on behalf of others was boundless, and most generously exercised, but he could secure no preferment for himself. A very clear light upon all his movements and his sentiments is presently thrown by the famous *Journal to Stella*, a correspondence kept up with Esther Johnson and Mrs. Dingley from Sept., 1710, to Apr., 1713. Of his profusion of political pamphlets poured out at this time, the best known is *The Conduct of the Allies*, which, published in Nov., 1711, went through four editions in one week. This gives, however, a very poor idea of Swift's importance in English politics during the administration of Harley. When he returned to London from a temporary retirement at Laracor in Sept., 1710, he was received by the Whigs with enthusiasm; but they had failed him before, and he repulsed their advances and rejected their "clumsy apologies." He threw in his lot with the Tories, and was received into the innermost councils of the new ministry. A satire, *Sid Hamel's Rod*, on the fallen Godolphin, enjoyed a prodigious success, and in Nov., 1710, Swift took the editorship of the Whig newspaper *The Examiner*, and made it the organ of the new Tory party. He proved himself a journalist of the very first order. His success culminated in the ministerial crisis of Dec., 1711, and he found himself one of the most powerful men in England. His health, indeed, began to trouble him, but throughout 1712 "Dr. Swift was the principal man of talk and business" in London. He was able to secure for his friends and protégés all the places and the favors they required; yet in the midst of his greatness his old ill luck assailed him, and in spite of his authority with the ministry he was refused the bishopric of Hereford. This was a blow to him, but he recovered from it; the death of Queen Anne in 1714 annihilated his hopes. As Arbuthnot said, Swift was "like a man knocked down," and in wrath and bewilderment he retired to Dublin. His fall was broken by his having been appointed in the previous summer to the deanery of St. Patrick's. His spirits languished in this enforced retirement, and his relations with Stella and with Vanessa (Miss Vanhomrigh) became closer and more mysterious. In 1716, so it has been alleged, Swift secretly married the former, and the latter died in 1723, in consequence of the furious resentment showed by Swift at her having endeavored to force the secret from Stella. Meanwhile Swift interested himself in the local politics of Ireland, and, having outlived the dislike which he originally inspired, became the most idolized of patriots. His political writing culminated in 1724 with the publication of the *Drapier's Letters*, in which he attacked the currency scheme for allowing a William Wood to supply Ireland with a copper coinage. The vogue of these *Letters* was so great, and the indignation they aroused in Ireland so vociferous, that the Government withdrew Wood's patent, and failed in an attempt to prosecute the author. Swift's popularity in Dublin knew no bounds, and when George II. came to the throne it was hoped by his English friends that the dean would recover his influence; but a visit to London in 1727 had no result, and Swift went back for good to "wretched Dublin in miserable Ireland." Two years later his foiled ambition made him describe himself to Bolingbroke as ready to "die here in a rage, like a poisoned rat in a hole." Meanwhile he had been more fortunately engaged in certain literary labors. As early as 1722, at least, he had received Pope's encouragement in the outline of a satire on society, which was to take the form of "very extraordinary voyages into very extraordinary nations," and to "manifest the most distinguishing marks of a philosopher, a politician, and a legislator." He brought the completed MS. of this work, the famous *Gulliver's Travels*, to England with him in 1726, and it appeared anonymously during the succeeding winter. With the exception of Defoe's *Robinson Crusoe*, which had been issued seven years earlier, no romance had been written in English

which approached this wonderful book in originality or vigor. The first hint of the design has been traced to Pope's *Monodies of Scotland*, while the legend of Archibuteus has been detected in the speculations of the third party; it is plain that the whole scheme had been discussed in the literary salons of men of letters with whom Swift took to associate in London, and from whom he derived still so tellingly the names. It has been conjectured with probability that the voyage to the Country of the Hairyman was written during the last illness of Stella, and that the mental anguish of the author gave force to this appalling satire; but although after the summer of 1729, Stella ceased to be capable of companionship, she lingered until Jan., 1738, Swift then hated Dublin more than ever; he described it as his "crucible, dirty dog-hole, and prison," and could give the despatch of St. Patrick's no higher praise than that it was "a place good enough to die in." He adopted of set purpose a contemptuous attitude toward literature and politics. Yet he continued to write some of the most highly finished and forceful of his compositions, especially in verse. Of the latter class are *The Journal of a Modern Lady*, which dates from 1729; *The Lady's Dressing-room* (1730); the admirable and extraordinary tale on the death of Dr. Swift, finished in 1731; *The Beasts' Confession* (1732); and, best of all, the vigorous "rapody" *On Poetry* (1733). It is believed that about 1729 he wrote what has been called the "extraordinary passage of willfully insane chatter," *The Polite Conversation*, which was published by Mrs. Barber in 1728, soon after the version, which had so long distressed him, combined with the distress of deafness and melancholy to cloud his reason. An accident which, Mrs. Whiteway, finding him at the mercy of servants, came to take care of him, but he became hopelessly insane. From 1744 to 1748 Swift was a raving maniac, under restraint; he then sank into a sort of stupor, the rigor of his constitution long supporting his frame and lengthening the struggle. At last on Oct. 19, 1745, he died in Dublin. He was privately buried in St. Patrick's, and when his will, drawn up in 1740, was opened it was found that he had left his fortune to endow a lunatic asylum for Ireland, wishing to

show by one satire-truth
No lunatic needed it so much.

The personal character of Swift deeply impressed the age, and innumerable anecdotes preserve the tradition of his wild humor, his tumultuous bursts of arrogance, his admirable perspicuity, and his curious inconsistencies of conduct and temper. His person was athletic and commanding; his eyes of the clearest blue, and all his life he was endeavoring by violent exercise to subdue his mysterious physical malady. History has dwelt to excess on his ferocity, and has said too little about his prevailing charm of address, his occasional but exquisite outbursts of sympathy. In literature, although he scarcely produced anything that was not more or less of an occasional nature, his is the greatest figure between Dryden and Johnson. The earliest life of Swift was that published in 1751 by Lord Ormsby. This book contained valuable documents, but was prejudiced and inaccurate, and it was supplemented by a very important volume of *Observations*, by Dr. Delany, in 1754. Hawkesworth first collected the works in 1764. In 1785 Thomas Sheridan, the son of one of Swift's most intimate friends, published a life, although his personal knowledge of the dean had been very slight. Sir Walter Scott founded upon these and other materials his entertaining *Life of Swift* in 1814, and published a very full and excellent edition of the works, which he still further improved in 1824. John Foster published a fragment of a yet more minute biography in 1875, and among later writers on Swift, Leslie Stephen (1882) and Henry Craik have been the most competent. In 1893-94 a new issue of Sir Walter Scott's large edition of the works was published.

ELIZABETH GREEN.

Swift, Lewis: astronomer; b. at Clarkston, N. Y., Feb. 20, 1820. He was first a business man, began studying astronomy in 1850, and constructed a telescope; gave special attention to comets, and discovered comets in 1862, 1869, 1874, etc. For these discoveries he received in 1882 the Lalande prize from the French Academy of Sciences. He also received three gold medals from the Imperial Academy of Sciences at Vienna. He removed to Rochester, N. Y., in 1879, and became director of the observatory there, specially fitted up for him by the citizens. In 1894 he removed his instruments to Echo Mountain, Cal., in order to get the advantage of the purest air of the Pacific coast.

S. S.

Swift, William Henry: engineer; b. at Taunton, Mass., Nov. 6, 1800; was a cadet at the U. S. Military Academy from 1818 to 1819. He was assigned when a cadet to Maj. Long's Rocky Mountain expedition, with which he served until 1821, having meanwhile (1840) received his commission as second lieutenant of artillery; from 1821 to 1829 served on topographical duty in making surveys of military defenses of the Atlantic coast, of the Chesapeake and Ohio Canal, of the Florida Canal and rivers and harbors of the Gulf of Mexico; in constructing a map of the post-offices and postroads of the U. S.; and surveyed several railways. In 1832 was appointed brevet captain and assistant topographical engineer, and for ten years was employed as assistant in the U. S. coast survey upon the Atlantic coast, being in charge of river and harbor improvements from Maine to Connecticut 1847-48; from 1848 to 1849 was also resident and constructing engineer of the Massachusetts Western Railroad, from Worcester to the western boundary of Massachusetts, becoming captain topographical engineer, July, 1852; was assistant to the chief of topographical engineers 1848-49; was engaged 1847-49 in constructing the lighthouse at Minot's Lodge, Massachusetts Bay, which was destroyed by a great gale in Apr., 1851. In 1845 he resigned from the army. D. in New York, Apr. 7, 1879.

Swift, Zephaniah, J. D.: jurist; b. at Wareham, Mass., in Feb., 1759; graduated at Yale College in 1778; studied law, and practiced at Wareham, Conn.; was Representative in Congress (1794-97); appointed judge of the Supreme Court of Connecticut in 1801; was chief justice 1800-19, was several times elected to the State Legislature, a delegate to the Hartford convention, and a member of the commission to revise the laws of the State. He published an outline on *Domestic Slavery* (Hartford, 1791); *System of the Laws of Connecticut* (1795-96); *Digest of the Law of Evidence in Civil and Criminal Cases and a Treatise on Bills of Exchange and Promissory Notes* (Hartford, 1810); and *Digest of the Laws of Connecticut* (1822-23; new ed. 1845-53), which last work is the standard treatise on that subject, and is often called the Connecticut lawyer's Blackstone. D. at Warren, O., Sept. 27, 1823. Revised by F. SIMMONS ALLEN.

Swimming (O. Eng. *swimman*, swiia; O. H. Germ. *swimman* (> Mod. Germ. *schwimmen*), float, swim; Lat. *swimmus*); the act of progressing in the water by means of strokes with the hands and feet. As the specific gravity of the human body is only slightly greater than that of water, swimming is easily learned, with or without an instructor. The density of salt water being greater than that of fresh, it is much easier to swim in it. Indeed, if the saturation is very great, as in the Dead Sea or the Great Salt Lake, the specific gravity is greater than that of the human body and a man can not sink in it.

A great variety of mechanical devices have been in use both to assist in acquiring the art and for making swimming safer, easier, or more rapid; but the presence in the water of a competent instructor to give the necessary support will give better results in the beginner than any attachment of floats or other supports which buoy the body too high in the water, and teach the swimmer to place his dependence on something other than his own buoyancy. One of the best methods in beginning is to wade out until breast-deep in the water, turn toward the shore, and throw a white pebble or any other object easily discernible a short distance before him and plunge after it. The resistance offered by the water to this effort will buoy him up, and the moment he has acquired sufficient confidence and command of his limbs to strike out regularly, he has learned to swim. The common forms of stroke are the broad, dog-paddle, and side, or Indian. The first two are much the more natural and easy to acquire. In the broad stroke after bringing the body nearly horizontal, the arms and legs are drawn slowly toward the body and then extended alternately, with a quick and strong impulse. The hands should be kept flat and the fingers closed, the legs should be well apart at the beginning, and at the conclusion of the act of kicking brought together. In the tread the body is kept perpendicular and hands and feet beat downward. In the dog-paddle the body lies nearer horizontal, and hands and feet are moved rapidly and alternately with a paddling movement. The side-stroke is found represented in mosaic in Pompeii, and was popularized in England by Tredgden. It is the stroke commonly used in racing, and consists, briefly, in turning the body on one side and reaching far ahead with the under hand while the other sweeps by the chest and belly.

Swimming races, especially in Great Britain, have become carefully regulated athletic events. Prior to 1869 there were few clubs to manage these contests, but on Jan. 7 of that year a swimming congress met at the German Gymnasium, King's Cross, London, where was formed an amalgamation called the Associated Metropolitan Swimming Clubs. The name was changed shortly after to the London Swimming Association, and again changed in 1874 to the Swimming Association of Great Britain. The Amateur Swimming Association of Great Britain was formed Mar. 3, 1886. It has a membership of over 300 clubs, and is the largest organization of the kind. New Zealand and New South Wales both have flourishing amateur swimming associations, the former being formed in 1890.

Both Oxford and Cambridge have clubs with intercollegiate and inter-varsity matches, and official recognition of swimming as a subject of instruction was secured in the elementary board schools in England in 1891.

This art is not so general in the U. S. as in Great Britain, nor is club organization at all thorough.

E. HITCHCOCK, Jr.

Swinburne, ALGERNON CHARLES: poet; b. in London, Apr. 5, 1837; son of Admiral Swinburne; received his education partly at Eton, partly in France, and in 1857 entered Balliol College, Oxford, where he remained only a short time. His life has been mainly spent in London. He has published *Rosamond* and *The Queen Mother*, two dramas (1861); *Atalanta in Calydon*, a tragedy constructed after the Greek model, in which he first manifested his peculiar powers (1864); *Chastelard, a Tragedy* (1865); *Poems and Ballads*, which were so severely criticised for their erotic character that the English publisher endeavored to suppress them, and which were put forth in New York under the title *Laus Veneris* (1866); *A Song of Italy* (1867); *Ode on the Proclamation of the French Republic* (1870); *Songs before Sunrise* (1871); *Bothwell* (1874), a dramatic sequel to *Chastelard*; *Essays and Studies* (1875); *Studies in Song* (1881); *A Century of Roundels* (1883); *Life of Victor Hugo* (1886); *Lochner, a Tragedy* (1887); *The Sisters*, a tragedy (1892), and other works. See ENGLISH LITERATURE.

Revised by H. A. BEERS.

Swine: any artiodactyl mammal of the family Suidæ (*q. v.*). The wild species of *Sus* are variously enumerated by zoölogists. Of these, the wild boar (*Sus scrofa*) of Europe, North Africa, and Asia Minor is the best known, and is generally regarded as the original of the common domestic forms. The validity of many of the other species, which are found mostly in the East Indies, is open to question, as they may be feral descendants of introduced domestic specimens. A small species (*Sus salvianus*) of Nepal, the Terai, and Bhutan has been separated generically as *Porcula*. The river-hogs of the genus *Potamochoerus*, the babirusa, and the wart-hogs are other swine. The chief seat of the world's swine-rearing industry is in the more northerly States of the Mississippi valley, where favoring conditions of soil and climate encourage the production in enormous quantities of Indian corn, which is chiefly relied on to feed the swine during both their growing and fattening periods. In the U. S. swine, when very young, are designated as pigs, when partly grown as shotes, and later as hogs. In Jan., 1895, the number of swine in the U. S., as given by the Department of Agriculture, was 44,165,716, worth \$219,501,267; of these, Iowa alone had 5,516,485, or 50 per cent. more than the United Kingdom, which in its numbers does not vary widely from Missouri. In the U. S. the number doubled in seventeen years following 1876. Prior to 1850 swine had little uniformity except that they were white and slow in maturing; there were innumerable varying breeds, each a favorite in some county or section of a State, and those growing to the largest size were esteemed best, regardless of excessive offal or cost of production. At present nine-tenths of the hogs in the U. S. are black, with small markings of white on the face, feet, and tail, and sometimes elsewhere. These are of the Poland-China and Berkshire breed, or a mixture of the two; the next most

prominent breed is the Chester White. Other breeds, equally distinct, but reared in limited numbers, are the Essex, black; Duroc-Jersey or Jersey, red, sandy, or reddish; Victorias and Suffolks or Small Yorkshires, white. The Essex and Yorkshires are from England, the Duroc-Jerseys are of uncertain origin, and the Victorias originated since 1860 in Indiana. The predominant breed, the Poland-China, originated in Butler and Warren cos., O., between 1838 and 1840 in the crossing of various families there known as Big China, Russia, Byfield, Bedford, and Irish Grazer, and the offspring was a large black and white spotted kind called by many names, from which a national convention of swine-breeders in 1872 selected that of Poland-China. These were crossed with imported Berkshires to give refinement and propensity to earlier fattening, and incidentally they acquired the Berkshire's black color and white markings. The Berkshire in its improved form originated (as did the Essex) in England—Italian and Spanish swine being crossed with the coarser native stock—between 1780 and 1800, but although first introduced into North America about 1830 it did not obtain general favor until 1870-80. Chester Whites are the result of mating some large white stock from Bedfordshire, England, with the white hogs common in Chester co., Pa., about 1818-30; the descendants being swine that gradually improved by selection, and have maintained their popularity in North America better than any other of their color. Hogs of a dark color are most largely reared because of a belief that they are harder and less susceptible to affections of the skin incident to sudden changes of temperature and the muddy quarters, severe winds, and burning suns to which they are too often continuously subjected. Poland-Chinas, Berkshires, Chester Whites, and Duroc-Jerseys are classed as large breeds, weighing, when properly reared, from 300 to 450 lb. at twelve months, and from 500 to 600 and even more at eighteen months, and they have been bred to a degree of fineness in bone, smallness of offal, compactness of form, and early maturity which makes them well-nigh perfect. Essex, Victorias, and Suffolks or Small Yorkshires are termed small breeds, and, although of excellent quality, do not grow to such weights as others, and mature more quickly.

Preparation of Hog Products.—The two principal markets, slaughtering and packing points, for swine are Chicago, Ill., and Kansas City, Kan. There were marketed in the former city in 1894 7,483,228 head, and in the latter 2,547,077. Chicago packed in the year ending Mar. 1, 1895, 5,293,202, and Kansas City, 2,105,333; these numbers have been largely exceeded in some previous years when the supply was more plentiful. The average live weight of 16,003,645 hogs packed in the U. S. in the year ending Mar. 1, 1895, was 231.22 lb.; average weight of their lard, 33.31 lb.; and average cost alive, \$4.67 per 100 lb. Careful calculation of the per capita rate of domestic consumption in recent years indicates 55 to 57 lb. of pork and about 8 lb. of lard. Next to cotton and wheat the swine interests furnish the largest values in exports from the U. S., which for the year ending June 30, 1894, were as follows:

Bacon and hams.....	503,628,148 lb.
Pork.....	64,744,528 lb.
Lard.....	447,666,867 lb.
Total.....	1,015,939,543 lb.
Value.....	\$93,433,532
Average per pound.....	9 19 cents.

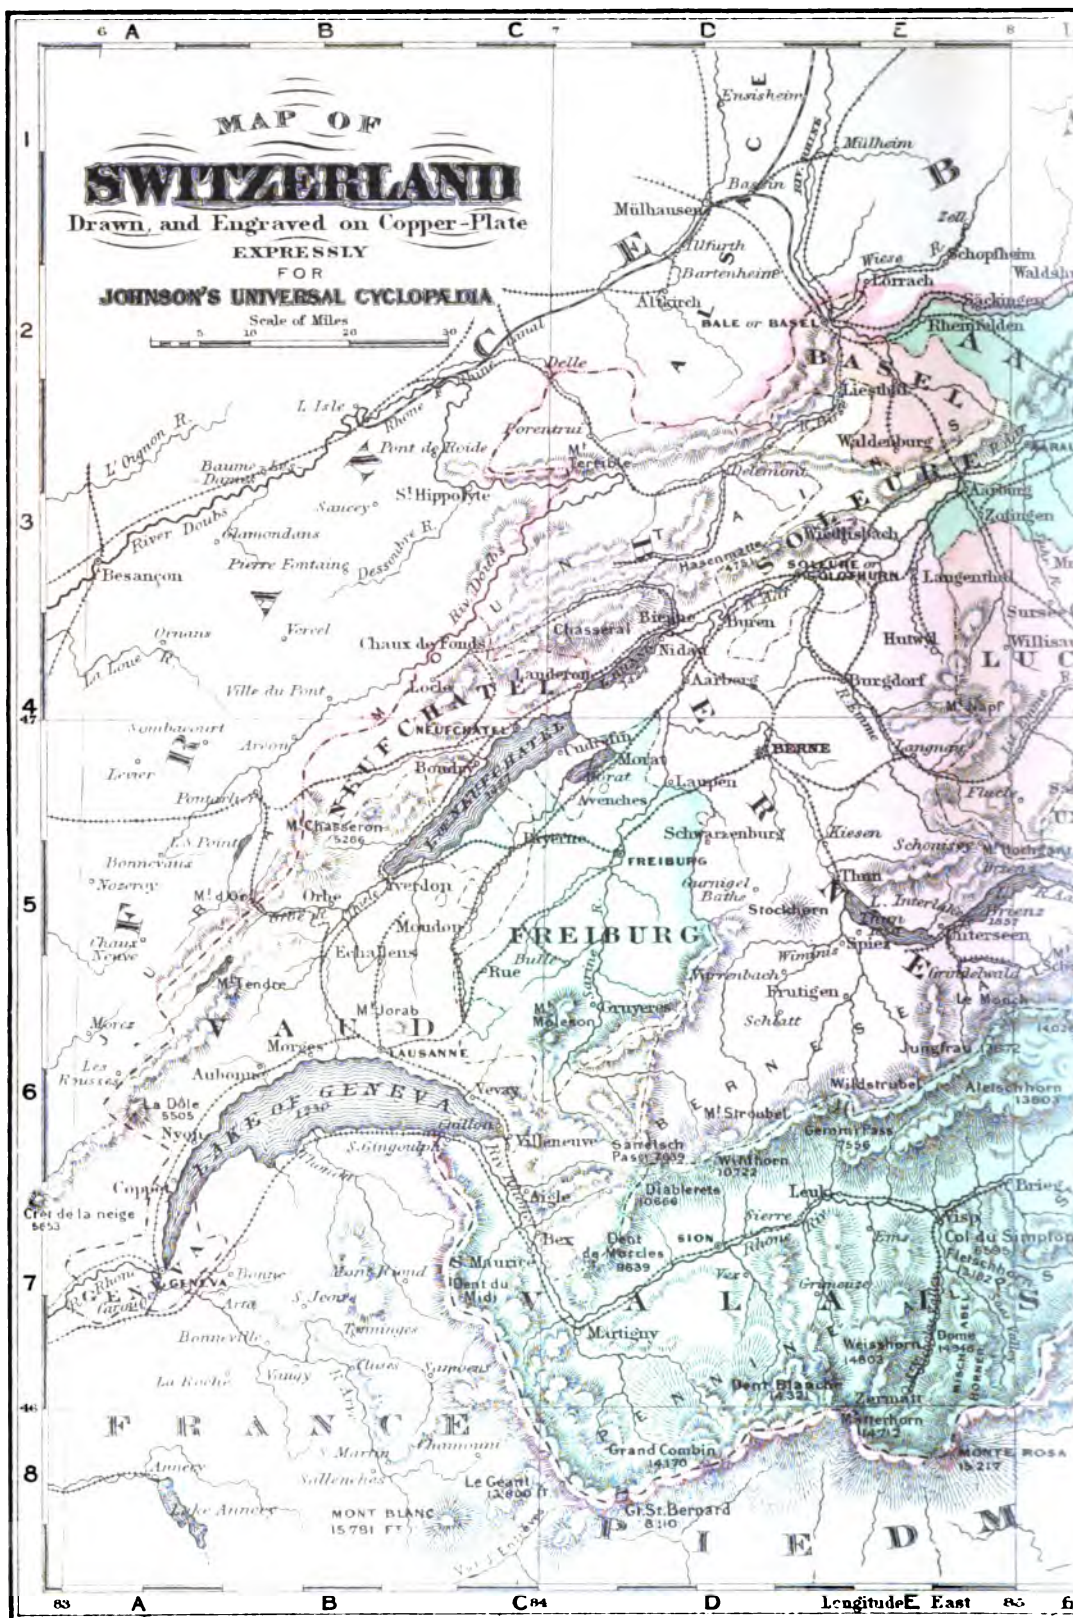

Counting on the customary basis of 175 lb. of product to equal one hog, the exported product for the year mentioned was equivalent to 5,805,369 hogs. Of the total exports for the twelve months indicated the United Kingdom purchased the following quantities:

Bacon and hams.....	408,979,637 lb.
Pork.....	14,273,057 lb.
Lard.....	149,691,950 lb.
Total.....	572,944,653 lb.

The British provinces of North America pack annually from 350,000 to 500,000 hogs, and import from the U. S. from 30,000,000 to 65,000,000 lb. of product. All other countries of the world produce from 40,000,000 to 45,000,000 swine, of which Russia has one-fourth, followed by Germany, Austria-Hungary, France, and Spain respectively, which have from 7,000,000 to 4,000,000 in the order named. They give but little attention to breed, quality, or pedigree. In the five years ending with 1840 the U. S. sold in Europe hog products to the value of \$1,533,522 annually, or the equivalent of 92,154 hogs at \$16.65 per head. Forty years later the

TILDEN FOUNDATIONS.

swine for a single year equalled 7,049,000 head, worth \$104,000,000, or \$14.95 per head. In 1900 hog products exports had increased 700 per cent., and in 1900 nearly 7,000 per cent. Since 1901 all swine products imported for export have been inspected at the point of slaughter as to genuineness—and especially freedom from trichinae—by veterinarians and inspectors appointed by and under supervision of the U. S. Department of Agriculture. The chief scourge among swine is a contagious fever little understood as to cause or treatment, popularly called chills, which each year rages in various localities, destroying entire herds, including those supposed to be in the best condition, amounting to millions of dollars in value. Feeding sanitary and hygienic surroundings, and insufficient variety of food leading to an unbalanced constitution, are regarded as encouraging its development. Its incubation is from one to two weeks in mild weather and three or four days in warm. It is fatal in from one to six days, or, in a few, uncertain, or unsatisfactory recovery. P. D. Cameron.

Swilag, David, clergyman; b. in Cloonagh, U. Aug. 29, 1829; graduated at Miami University, Oxford, O., 1859; studied theology, taught Greek and Latin, and became principal of the classical school of Miami University; became pastor of the Fourth Presbyterian church in Chicago 1869; was called for heresy in 1874, and acquitted by the presbytery, but became an independent minister, and pastor of Central church, Chicago. He was an editor of *The Alliance*, and published *Old Essays* (1899) and other works. D. in Chicago, Oct. 8, 1894.

Swinton, John, journalist; b. at Salton, Scotland, Dec. 12, 1820; brother of William Swinton. Emigrated to Canada and then to the U. S. in 1841; was educated at Williamstown Seminary, Massachusetts; removed to New York in 1857, where he was connected editorially with the *Times*, and afterward with *The Sun*. In 1862-67 he published *John Swinton's Paper*, a weekly journal in the interest of labor reform. He has written and lectured much on various aspects of the labor question, and has published among other pamphlets: *New Issue: the Chinese-American Question* (New York, 1870); also *A History on Henry J. Raymond* (1870); *John Swinton's Travels* (1880); and *A History on John Brown* (1881). H. A. Barker.

Swinton, William, A. M., author; b. at Mallan, Radnorshire, Scotland, Apr. 23, 1822; removed to the U. S. in 1843; studied at Knox College, Toronto, and at Auburn College; in 1854 taught in a female seminary at Greensboro, N. C., and subsequently in a private school in New York; during a considerable part of the civil war was the correspondent, mainly with the Army of the Potomac, of *The New York Times*; in 1869 received the degree of A. M. from Amherst College, and in 1869 was appointed Professor of Belles-Lettres in the University of California. In 1874 he resigned and went to Brooklyn, N. Y., where he prepared text books. For three he was awarded a gold medal at the Paris Exposition of 1867. He published *Rambles among Words* (New York, 1859; London, 1861); *Campaigns of the Army of the Potomac* (1864; revised ed. 1866); *The Pocket Dictator: Battles of the War* (1867); *The History of the New York Seventh Regiment during the War of the Rebellion* (Boston, 1870); *Word Analysis* (1872), and other works. D. in New York, Oct. 24, 1892.

Swiss Guards: bodies of mercenary Swiss troops employed as body-guards and for duty about courts. Swiss mercenaries have frequently been hired by foreign powers since the time of the Swiss struggle for independence, which brought the valor and hardihood of that people into notice. The term Swiss Guards, however, especially refers to the royal body-guard of the kings of France. This force, which was organized in 1616, showed remarkable courage and loyalty in the service of the Bourbons. In 1793 they were courageously handled by a mob, and Aug. 10, 1793, almost every man was killed in the heroic defense of the Tuilleries. They numbered about 2,000. Their heroism is commemorated by Thierwalden's *Lion of Lucerne*, carved from the living rock in a cliff near one of the gates of Lucerne. Louis XVIII. reorganized the Swiss Guard in 1815. In the Revolution of 1830 they were defeated and dispersed. P. M. Uxley.

Swiss Stone-plant. See *GERANIUM PIVET*.

Swithin, Swithun, or Swithum, SAINT: bishop and patron of Winchester; is of noble parentage; became a monk in the Old Monastery in Winchester; later proved a pious disciplinarian to Egbert, King of the West Saxons; his

services and tales to the king's son Ethelwold and later his services also; Bishop of Winchester 852. He was remarkable for piety and great activity in building churches. D. at Winchester, July 2, 892. "His body was buried, according to his order, in the churchyard, where his grave might be visited on by passengers" (*Boetes*). In 871 his relics were transferred to the church. On this translation "such a number of miraculous cures of all kinds were wrought as was never in the memory of man known to have been in any other place." One of his arms was "kept in the abbey of Peterborough." His day in the Roman calendar is July 2—his feast-day—in the English calendar July 15, the day of the translation of his relics, and it is commonly said in England that if it rains on St. Swithin's day it will rain for forty days thereafter, a saying which is supposed to have originated in the alleged fact that the translation of Swithin's remains was delayed by heavy rains. See John Earle, *Illustrated Fragments* (London, 1861) and Butler's *Lives of the Saints* under July 15. August MacCarthy, London.

Switzerland or Helvetic Confederation [*Suetio*—from *Suetis*, *Solvetis*, a Swiss, derivative of *Schwiz*, Switzerland; of *ty*, *le Suisse*, Ital. *Svizzera*, Switzerland]; a confederated republic of twenty-two cantons, occupying the Alps, between Germany, Austria, Italy, and France; of oval form, 221 miles long E. and W., and 140 miles broad N. and S.; boundary irregular and only in part inland. Area, 15,920 sq. miles.

Physical Features.—It occupies the Central and Northern Alps; the Western are in France, the Southern in Italy, and the Eastern in Austria. The highest point is Mont Blanc (15,781 feet), at the angle of France, Italy, and Switzerland. The proper central mountain is Monte Rosa (15,217 feet), 45 miles E. on the Italian boundary. The hydrographic center where arise the Rhone flowing through the Po to the Adriatic, the Rhine flowing to the Gulf of Lyons, the Rhine flowing to the North Sea, and the Inn flowing through the Danube to the Black Sea is St. Gotthard, 60 miles farther N. E. The chief range is the Pennine Alps, making the western part of the southern boundary; N. of it and nearly parallel is the range of the Bernese Alps with the Rhine valley between them, and containing peaks somewhat lower (Piz, 14,046 feet, and Jungfrau, 13,678 feet). To the E. the main ranges are in the Rhetic Alps with culminating point at Mt. Bernina (13,991) on the Italian frontier. (See Alps.) The plain of Switzerland lies on the N. W., between the Jura Mountains and the Alps, and between Lake Geneva and Lake Constance; average elevation, 1,200 to 1,500 feet, between it and the Bernese Alps is the higher plateau called the Bernese Oberland. The remainder of the inhabitable part of the republic consists of mountain valleys and lake margins, sometimes with small alluvial plains, but often narrow, wild, and inaccessible.

The chief river is the Rhine, which winds around the northern side of Switzerland and penetrates to St. Gotthard from the E. With its tributaries it drains over 70 per cent. of the area and most of the lakes of the country; length in Switzerland, 216 miles. The Rhine leaves at the W., is 71 miles long in Swiss territory, and drains 16 per cent. of the area. The Inn leaves at the E., has 54 miles in the confederation, and drains 9 per cent. of the area; and the Po sends the Thimo 44 miles into Swiss territory and drains 3 per cent. A small part of the southeast is drained by the Adige.

Many beautiful lakes are situated in whole or part within Swiss territory. Some details as to the largest of these are tabulated below:

NAME.	From Lake.	Area in sq. miles.	Mean depth of surface, feet.	Greatest depth, feet.
Genève	Alpine	220	1,384	1,537
Constance	Alpine	220	1,300	1,430
St. Gallen	Alpine	10	1,407	475
Lake Maggiore	Alpine	40	666	1,400
Lucerne	Alpine	44	1,354	865
Uri	Alpine	11	1,341	405
Uri	Alpine	10	860	300
Uri	Alpine	10	1,407	718
Uri	Alpine	10	1,404	500
Uri	Alpine	10	1,385	1,021
Uri	Alpine	10	1,307	800

The lake area of Switzerland is 550 sq. miles, but the area of glaciers (perpetual ice and snow) is 710 sq. miles. This is confined to eleven cantons and principally to four—Uri, Valais (204 sq. miles), Uri (180), Bern (111), and Uri

(44). The Swiss glaciers number 471, and of these 138 are of the first rank (having a length of $4\frac{1}{2}$ miles or more). The largest is the Aletsch, on the southern slope of the Jungfrau, 15 miles long and covering 42 sq. miles. The Pennine Alps alone have 140 or more glaciers, and the Rhône, just N., is fed by 263. The lowest point reached by a glacier in Switzerland is 3,225 feet, in 1818 by the Grindelwald on the northern slope of the Jungfrau. The line of perpetual snow varies between 9,023 feet and 9,259 feet. The Aletsch begins at 9,820 feet and descends to 5,000 feet. The Eastern Alps have many glaciers, but they are generally of the second rank. See GLACIERS.

Geology.—Notwithstanding the mountainous character of Switzerland its geology is simple. Eruptive rocks are few and belong to very early geologic times. The core of the Central Alps is made up of primitive, azoic, crystalline rocks, and these make the ridge of this roof of Europe. To them are applied a series of schistose Carboniferous rocks semi-crystalline in character. The Triassic is found only at the east and west ends of this ridge. The whole was raised out of the sea in Jurassic times (named from the Jura Mountains on the N. W. of Switzerland), and the Jurassic rocks are applied next outside the Carboniferous composing some of the secondary ranges. In them are found some of the most interesting fossils ever discovered. Next in succession from the azoic ridge are found well-developed layers of Cretaceous and then extensive Tertiary beds, especially the Miocene. The Glacial period and the more recent glaciers have left their traces and remains over all Switzerland, and the alluvial work of the present age has been and is still active in filling up lakes and making plains.

Climate.—The Swiss climate has been studied with special care, and presents features of great interest. There are four meteorological stations at heights from 6,290 to 8,215 feet, and the Mont Blanc station is just beyond the boundary. The southern slope is remarkably mild, but the northern part has a rigorous continental climate. The mean temperatures run from 35° F. to 55° in the inhabited portions, about equal to the range from Winnipeg to Cape Charles in North America. The decrease of temperature with each 1,000 feet of increased altitude is 3·2° on the northern slopes and 2·8° on the southern. The contrast of the seasons is greatest in the valleys, where winter temperatures of -25° F. sometimes occur. The precipitation is large (40 to 60 inches), and is greatest at an elevation of about 6,500 feet. The run-off is particularly large, and causes rapid and sometimes destructive accumulation of sediment and wash. The most noteworthy wind is the foehn, which, coming from southerly directions, descends on the leeward side so dry and warm that the snow disappears as if by magic, and the parching greatly increases the danger of fires.

Like the temperature, the population decreases with the height. There are no villages beyond 5,000 feet, except the little hamlet of Juf at 7,000 feet, the highest in Europe. On the Great St. Bernard the hospice is at 8,110 feet, and the Alpine Club has some retreats, the highest of which (on the Matterhorn) is at 12,800 feet. The inhabitants of the high valleys have larger bodies and feet than those below, and are more free from several maladies, notably phthisis. Pneumonia and pleurisy are more common and more dangerous than below, as are also asthma, scrofula, and rheumatism. In the deep, moist valleys, with little sunshine, goiter and cretinism occur in large ratio, but increasing attention to cleanliness and general comfort diminishes this.

Natural Productions.—Switzerland is not productive in metals. There are several mines of anthracite, lignite, ordinary coal and salt, and one of graphite. Quarries of building-stone are more numerous and important. The flora falls easily into five zones, defined by the elevation; the zone of the vine goes up to 2,000 feet; that of cereals to 3,000 feet, and includes most of the plain; that of the forests to 6,000 feet; the sub-Alpine to 8,000 feet; and the Alpine above 8,000 feet. The arable land is chiefly confined to the first two. The forests occupy 3,032 sq. miles of area, and include the oak, beech, and spruce. They are valuable not only for the ordinary uses of trees, but also to protect the lower levels from destructive overflows; forestry is carefully practiced. Peat exists in large quantities, and forms an important resource for fuel. The sub-Alpine zone is rich botanically; in the Alpine region a species of violet and the much-praised edelweiss reach the very margin of perpetual snow.

The fauna is not rich, and animals suitable for hunting are protected by stringent game-laws. Wolves and deer are

very rare; a few bears still remain in the wilder recesses of Valais and the Grisons; the wild boar survives in the Jura; the chamois can be hunted only twenty days in the year, and is increasing in number; the fox is common. The best-known bird is the lammergeier. Fish are very abundant, and fish-culture is much practiced.

Agriculture.—Of the total area 72 per cent. is classed as productive, and of the productive part 36 per cent. is in grass and meadow, 29 in forests, 19 in fruit, and 16 in crops and gardens. There are about 300,000 peasant proprietors, representing 2,000,000 of the population. Rye, oats, and potatoes are the chief crops, but the importation of foods is large. Cheese and condensed milk are manufactured in large quantities for export. About 22,000,000 gal. of wine are produced annually. In 1886 there were 98,333 horses, 1,211,713 cattle, 341,632 sheep, 415,619 goats, and 394,451 swine; and in 1893 there were imported 10,198 horses, 65,199 cattle, 51,386 swine, and 92,461 sheep.

Industry.—The soil does not yield sufficient for the support of the population, and a large percentage finds employment in industries, very generally small, occupying only the family. The larger ones subject to the factory law only are enumerated. Of these on Jan. 1, 1893, there were 4,606 devoted to the manufactures of textiles, leather, articles of food, chemical, metal and wood products, paper and printing, pottery, glass, watches, etc.

Switzerland has over 1,000 hotels, employing 16,000 people, representing a capital of \$64,000,000, and giving a gross annual income of \$10,500,000.

Population.—The population from 1880 to 1888 increased at the annual rate of 0·4 per cent. In 1888 it was 2,917,514; and there were 1,041 females for every 1,000 males. The density of population was least in the Grisons (34 per sq. mile), Uri (41·5), and Valais (50·3); greatest in the canton of Geneva (977), of Basel (674), and of Zurich (506); all of the latter have cities of considerable size. German is spoken by the majority, and is hence the official language in sixteen cantons, French in five, and Italian in one. In the Grisons about 46 per cent. of the population use German, about 40 per cent. Romansh, and 14 per cent. Italian. Italian and Romansh are receding, French is growing in use, and German remains about stationary. The official French is full of Teutonisms. The birth-rate is high, and 5 per cent. of the births are illegitimate. The annual emigration amounts to about 8,000, but is decreasing; the emigrants are generally agriculturists and unmarried. They are chiefly from Bern, Zurich, St.-Gall, and Ticino, and nearly all go to the U. S. There is absolute freedom of conscience; about 60 per cent. of the population is Protestant, the remainder Roman Catholic. The Protestantism is Calvinistic in doctrine and Presbyterian in government. Education is compulsory, primary education is free, and the percentage of illiteracy nearly evanescent. There are 5,000 schools of all grades, with 13,000 teachers and 542,000 pupils; also five universities (at Basel, Zurich, Bern, Geneva, and Lausanne, the last since 1891), with 400 teachers and 25,000 pupils, of whom nearly a half are aliens. The principal towns (with the communal population for 1893) are Zurich (103,271, including suburbs); Geneva (78,777, including suburbs); Basel, Basle, or Bâle (75,114); Bern (47,620); Lausanne (35,623); St.-Gall (30,934); Chaux-de-Fonds (27,511); Luzern or Lucerne (21,778); and Neuchâtel (16,772).

Commerce.—The effective imports (not in bond) for 1893 were valued at \$168,200,000, and the exports at \$131,400,000. The chief imports were foodstuffs, tobacco and spirits, silk, wools, cottons, and other textiles, metals, minerals, and chemical colors, bullions, and coin. The chief exports were textiles, timepieces, and colors. Wheat and flour are largely imported. The trade is chiefly with Switzerland's immediate neighbors, Germany first, but a considerable proportion of the exports goes to Great Britain and the U. S.

There were 2,220 miles of railway in operation in 1893, with a total cost of \$210,000,000, and a gross income in 1892 of \$18,150,000, and expenses of \$12,075,000; also 4,515 miles of telegraph and 4,088 miles of telephone line. The number of post-offices was 1,491.

The unit of money is the franc of the same value (about 20 cents) as that of France. Swiss coin makes only about 5 per cent. of that circulated; the remainder is chiefly Italian and French. The *pfund* = 1·10 lb. avoirdupois; the *centner* = 100 pfund; the *arpent* of land = 8·9 acres.

Cantons.—Switzerland is composed of twenty-two cantons, although the splitting of each of three cantons into two demi-cantons makes the total number of federative units

Republic and lasted four years. To that form of government succeeded a sort of league based upon federal principles. Under this constitution Switzerland recovered an appearance of peace, but the mediator of that "mediation act" (Feb. 13, 1803) was a meddlesome neighbor and a despotic ruler. The mediation lasted ten years, and came to an end at the fall of the French empire. The European reaction against France took place, and Switzerland had to participate in it; her soil was invaded by the allies, as it had been so often and so long by the French armies. By the Congress of Vienna (1815) her independence and neutrality were acknowledged and guaranteed. The spirit of self-preservation and sense of dignity developed in Switzerland, and new efforts were made to give the country a stronger and more independent basis. Switzerland was led to it by new internal disturbances and external occurrences—notably the revolutions in France in 1830 and 1848. In the latter year a new constitution was adopted without foreign interference; this gave place on May 29, 1874, to that now in force.

F. M. COLBY.

Sword [O. Eng. *sweord* : O. Sax. *sweord* : O. H. Germ. *meert* (> Mod. Germ. *schwert*) : Icel. *sverð*] : a weapon of offense, consisting of a long blade and a handle large enough for the grasp of one hand or, rarely, of both hands. The characteristic of the weapon is that the blade is not mounted on a long handle or staff, while yet it is larger than the dagger or poniard.

Sword is the general term, and includes weapons as unlike one another as the cavalry saber and the slender triangular-bladed court sword worn by gentlemen at the close of the eighteenth century. It is, however, well to separate the saber in all its varieties from the sword proper.

The *saber* has one edge only and has a thick, broad back. Toward the point a few inches of the back may be sharpened, though this is uncommon. The edge invariably curves backward to meet the back in a sharp point, which is practically a triangular point; moreover, the whole blade usually curves backward, the back concave and the edge convex. Some cavalry sabers are straight. The cavalry and artillery sabers of the U. S. service are slightly curved, the curve being about one in twenty. The northern nations of Europe in the early Middle Ages used sabers as well as swords; that is, both their long and their short weapons of this kind often had but a single edge and a broad back. These weapons, really long and heavy knives, were called *scramasaxes*, and were probably the arms most constantly in use. The celebrated Japanese weapon is curved about as much as the U. S. saber, but is mounted very differently on its handle. The Eastern blade slopes backward from the handle at the very point of junction, but the Western one is set so that the blade slopes forward. The Japanese two-handed saber had a blade about 3 feet long; this, or a somewhat shorter weapon, formed the principal badge of the Samurai or military class, and was worn in the sash with a much shorter weapon of almost exactly the same general form. These Japanese sabers deserve their great reputation, as the blades are of extraordinary, perhaps unequalled, excellence. The scimitar of the Mohammedan nations is a light saber with the blade very much curved backward, the curve of a Persian scimitar of the eighteenth century and earlier being one in seven or one in eight. In these the blade is set almost exactly tangent to the straight line formed by the handle. Earlier scimitars seem to have had the blade made heavier and broader near the point than at the hilt, perhaps with the view of striking a heavier blow upon armor; but so little is known of the system of fencing or saber-practice in use among the Moslem nations that this is only offered as a suggestion. The drawing cut with the sword arm kept bent, which is supposed to be the favorite manner of attack, would not seem to require a heavy blade or one weighted toward the point. The steel of which the scimitar is made is or affects to be of the famous steel of Damascus, that is, of a steel wrought in such a way that the surface is covered with delicate waving lines in its substance. A weapon almost exactly like the Mohammedan scimitar was carried by officers of high rank in the French service during the first republic. Oriental blades and Oriental scimitars complete were worn indifferently in exchange with similar weapons of French make. English field-marshal are represented as late as 1885 carrying sabers of a like curvature. A modification of the saber used only in some parts of India has its sharpened edge concave and the back convex. One form of this, the deadly *koukri* of the Goorkhas, is weighted toward the point. The *yataghan* of

the Mohammedan nations on the Mediterranean Sea, from the Danube to Morocco, has also its sharp edge concave; the form varies greatly. The cutlass is the saber shortened and roughly and cheaply mounted, as for sailors, both in the navy and in private service. The *düsack* or *tesack* is nearly the same weapon, and especially one forged in a single piece, the handle being a mere hole in a plate. This simple weapon was used in Germany in the later Middle Ages and down to the seventeenth century.

The ordinary hunting-knife, of which the famous American bowie-knife is one form, is a shortened saber; these weapons are to the saber what the European dagger of the Middle Ages is to the sword proper.

Swords among Ancient Nations.—The special weapon of the ancient Roman infantry was, at least after the beginning of the second century B. C., straight, double-edged, sharp-pointed, and much longer and heavier than had been in use in earlier times or at any time among the Greeks. Little is known of its exact character, as the steel blades have been destroyed by rust, but the general shape is known from such sculptured representations as are found on the columns of Trajan and Marcus Aurelius at Rome. The length of the blade may be put at from 20 to 24 inches. It was used mainly for thrusting, but we are not to imagine a legionary thrusting like a modern fencer with the hand high and the fingers uppermost; a more common way of "giving point" was certainly with the hand very low and the point higher, the thrust being upward. The bronze swords of the northern nations were often what is called leaf-shaped, that is, they were broad toward the point and narrowest at a distance of 3 or 4 inches from the handle, and symmetrical in shape, that is, both of the edges had the same elongated S-curve, but reversed, the two meeting at a sharp point. The sword of the Gauls at the time of the Roman conquest seems to have been sometimes of bronze, sometimes of steel; it was long, very heavy, and often retained the leaf-shape of earlier times. Among Eastern nations, whether ancient or modern, the most important weapon which can be called a sword is the Malayan creese. This has a blade about 18 inches long, sometimes shorter, sharp-pointed, and having on each side a waved edge, the undulations being very decided, one in five or one in six of their length. Another important peculiarity is the setting of the blade, often not at all in the prolongation of the handle, but at a decided angle with it, the angle varying in different weapons. These blades form a great contrast with the smooth, close-grained, highly finished Japanese blades. The Malayan steel is, as it were, a carrying further of the Damascus waved or watered steel; it is extremely rough and with depressions between the lines of the waving nearly like the graining of wood which has been exposed to the weather. The straight sword used by the Hamran Arabs in hunting as well as war seems to be of European origin, perhaps a lingering on of the knightly sword described below.

In the Middle Ages.—With the appearance of what is known as chivalry, after the firm establishment of the feudal system, the sword of the knight was broad-bladed and straight, symmetrical in shape. From the beginning to the end of the age of heavy armor and knighthood the peculiar weapon of the knight was the sword with a thin, flat blade and both edges alike. The well-known sword of Childeric, found in his tomb and now in the Louvre, could not have had a blade more than 18 inches long, judging by the sheath, which is in good preservation. The sword of the ninth century had a blade nearly or quite 3 feet in length. That of the twelfth century was often shorter. Some swords of the thirteenth century had a blade 45 inches long; but the sword of the knight, intended to be wielded by one hand, could hardly exceed this length, and when heavy armor was to be broken or wrenched apart a mace or a horseman's axe was used. The two-handed swords of the later Middle Ages may have been used on occasion by mounted knights; thus the famous bronze statue of King Arthur in the Church of St. Francis in Innsbruck, which dates from about 1520, is furnished with a sword whose grip has two distinct holds for the two hands; but the two-handed sword was essentially a weapon of foot-soldiers, having a blade 4 feet or more in length and a handle about 16 inches long, weighted at the butt to partly counterpoise the blade. It is probable that but little delicate sword-play was used during the Middle Ages. Each combatant struck hard and caught his enemy's blows on his shield or trusted to his armor.

In Later Times.—With the gradual disappearance of armor the gentlemen of Europe introduced swords which,

through still heavier, were much lighter than those of the fifteenth century. The rapier was brought into use by the Spaniards and adopted by men of family toward the close of the sixteenth century, and was as long as the knightly sword of an earlier time, but much lighter. The broad, thin blade of the knight's sword gave place to a much narrower blade in which can be seen the beginning of the thrusting sword of the seventeenth century. These, however, were the arms of the nobles and their imitators; the private soldier still carried a blade for cutting as well as thrusting, and this passed into the heavy broadsword of the seventeenth century, such as became famous in the hands of Cromwell's soldiers. A similar weapon, carried by the second Highlanders under Montrose and Charles Edward Stuart, is often called a bayonet, but this is erroneous. The bayonet proper was a large two-handed sword, such as is described in Scott's romance *The Fair Maid of Perth*.

The rapier had always a straight, narrow blade, and when used for systematic and military fighting, as in the duel, was generally accompanied by the dagger, which was held in the left hand and parried the adversary's thrusts. As the science of fencing was developed the dagger was given up and the sword became lighter and shorter. A duel under Louis XV. was fought with swords whose blades did not exceed 3 feet in length, and were sometimes two-edged and flat, sometimes three-edged or bayonet-shaped.

One very curious form of the sword was the hunting-sword of the seventeenth century and later—a thin, two-edged blade curved about like a saber, one edge convex, one concave. Such blades were from 16 to 24 inches long.

In modern armies officers of certain ranks are supposed to wear a slender straight sword. Thus in the U. S. army in the civil war staff officers should have carried such weapons, but they generally preferred a saber.

As the sword has always been the weapon of ceremony and the typical badge of a soldier and commander of armies, so words of honor and sabers of honor are often presented to successful officers. Moreover, swords of more ceremony are carried before officials of high rank, or are held by them on certain occasions; thus among the regalia of Great Britain is the scepter, or "pointless" Sword of Mercy, and the "Sword of Justice." Somewhat in a ceremonial way the *edgewood* or *walking-sword* of the eighteenth century was considered the distinctive badge of a gentleman.

The Hilt.—The sword-hilt consists of grip, guard, and pommel. The long tang forged with the blade, straight, tapering, and of square-edged section, passes through a hole in the guard, is covered by the grip, and is held fast at the end by the pommel, or else is held fast in the grip by pins or the like, while the pommel is put on separate. The grip is a mere enlarging and rounding of the tang, sometimes by laying plates of bone or wood against its sides, sometimes by means of a tube of wood or of shark-skin, or even metal. Wire is sometimes wound around the grip to allow of a firmer hold. The guard is the part that varies most. In Roman swords it was small, a mere plate sufficient to stop the edge of another sword which might slide along its own blade, but no more. The Japanese saber has but a small guard, approximately oval in shape, a flat plate of iron or bronze. The medieval sword had a large and long cross-guard, each arm of it several inches long; those of the two-handed sword sometimes a foot across. The most elaborate of all sword-hilts is that of the sixteenth and seventeenth centuries, which was applied to broadswords and rapiers alike: this had a very elaborate protection for the fingers and knuckles, consisting of several curved bars or of a plate of steel. In connection with this was a complicated cross-guard; that is to say, a fine and carefully made sword of 1600 would have a long cross-guard, a secondary or upper guard 8 inches farther toward the point of the blade and composed of rings or flat plates or "shells" one on each side, and a "knuckle-box" curving from where the cross-guard meets the grip to the pommel. Sometimes the guard took the form of a cap, with the open part toward the hand. Sometimes the knuckle-hilt was a bowl so solid and impierced as to hold liquid. Modern sabers have generally a curved guard which protects the knuckles and sweeps around to meet the pommel, in which it is secured. This is a mere modification of the knuckle-hilt, as above described.

See *Duméril, Die Kriegswaffen* (Leipzig, 1867; trans. into French and English); *Egerton Castle, Swords and Masters of Fences* (London, 1886); *Lacombe, Les Armes et les Armures* (Paris; by Boutelle, *Armes and Armures*, London, 1874); *La Collection Spitzer*, vol. xi. HUBBELL SCOURGON.

Swordfish—any fish of the family *Xiphiidae*, remarkable for having the upper jaw prolonged forward in the shape of a long sword. The common swordfish (*Xiphioides gladius*) ranges from the Atlantic coast of North America eastward to the Mediterranean. It is often from 10 to 16 feet long, has very fine scales, no ventral fin, a long broken dorsal fin, and a large and deeply forked caudal. It is a very rapid swimmer, and is said to assail the largest whales with its sword. It sometimes strikes ships with such force as to penetrate several thicknesses of plank, and the sword is frequently broken off and left in situ, but the fish which most often assaults vessels is a smaller species of the genus *Tetrapturus*. The swordfish is generally esteemed as food, and is taken by the harpoon, thus affording an exciting and dangerous sport, but is too scarce to be of much commercial value. The use of the sword is not clearly understood, so all probability the fish employs it in gaining its sustenance, but the precise method is not known. The food of the swordfish consists of mollusks, especially the squid, and of small fishes. See *Pinnacles*. Revised by P. A. LORAN.

Syagrius, s-a grē-ry: the last Roman ruler in Gaul; was a son of Egidius, from whom he inherited what is known as the kingdom of Syagrius, embracing the country around Soissons, between the Seine, the Marne, and the Oise. The Franks encroached upon his domains, and finally, under their chief Clovis, gained a decisive victory over him at Soissons in 486, thereby destroying the last remnant of Roman power in that region. Syagrius fled to Toulon, but was afterward surrendered to Clovis, by whose command he was put to death. P. M. COLAY.

Syl'aris (in G. *Sil'aris*): city of Magna Græcia, in Lucania: founded by Achæus and Trophonius about 720 B. C., 8 miles from the Tarentine Gulf, between the rivers Crathis and Syllaris, the modern Crati and Cauda. It rose rapidly to a great prosperity, founded other colonies—Pezdonia, Latis, and Sidrion—covered a space of 8 miles in circumference, and was notorious for the luxury and effeminacy of its inhabitants. In 510 B. C. Syl'aris was completely destroyed by the Crotonians and never recovered, but in 448 B. C. the descendants of the conquerors and exiled Syllarians founded the city of Thurri in the immediate neighborhood of the old site of Syl'aris. Revised by J. R. S. STEWART.

Syl'el, Heryman, van: historian; b. at Dusseldorf, Prussia, Dec. 2, 1817; studied at Berlin and at Bonn; became Professor of History at Marburg in 1844, and director of the Royal Prussian Archives in 1878. He has taken an active part in politics, having been a member of the Prussian Legislature and of the Prussian Landtag. Among his writings are *Geschichte des ersten Kreuzzugs* (1841); *Die Entstehung des deutschen Königtums* (1844); *Geschichte der Revolutionen* (1859-74; lang. trans.); *Die deutsche Nation und das Kaiserreich* (1892); and *Die Herrschaft des deutschen Reichs durch Wilhelm I.* (1895-96; lang. trans. 1897). P. M. COLAY.

Sycamore [by analogy of *sycomore* from G. Fr. *sycomore* (< Lat. *sycomorus* = Gr. *sykambos*, mulberry-tree; *akos*, fig + *akos*, black mulberry)] a tree (*Platanus sycamore*, or *Sycamoreus antiquorum*) which is a near relative of the fig. It is a widespread, shady tree, much planted in the Levant for its shade. Its light, fragile wood is reputed to be indestructible. Its fruit is inferior in quality to that of the fig, but is abundant and palatable. In some parts of the U. S. the buttonwood or plane-tree is improperly called sycamore, and in Great Britain that name is applied to a maple (*Acer pseudoplatanus*). Revised by L. H. BAILEY.

Sycamore: city (founded in 1866): capital of DeKalb co., Ill.; on the Chi. and N. W. and the Chi. and West. railroads, 56 miles W. of Chicago (for location, see map of Illinois, ref. 2-E). It is in an agricultural, dairying, and stock-raising region; has manufactures of agricultural implements, flour, water-motors, insulated wire, brick, tile, varnishes, furniture, carriages and wagons, and soap, works for preserving fruit and vegetables, and breweries; also 11 churches, 3 graded public schools, a seminary for young ladies, high-pressure water-works, electric lights, a national bank (capital \$50,000), a private bank, and a semi-weekly and a weekly paper. Pop. (1880) 6,028; (1890) 8,067; (1895) estimated, 9,400. EDITOR OF "THE SYCAMORE."

Syd'nam, THOMAS: physician; b. at Winford, Engln., Dorsetshire, England, in 1624; educated at Oxford, and in 1648 became a fellow of All Souls' College, having meanwhile served as an officer in the parliamentary army; studied

medicine at the college of Montpellier, France; took his degree of M. D. at Cambridge, and established himself about 1660 as a physician in London, where he soon attained the foremost place. He abandoned the mere routine system of practice then prevalent, basing his own upon the theory that there is in nature a recuperative power which it is the province of the physician to aid. He was especially acute in observing and describing the symptoms of diseases, and carefully studied the relations between epidemics and the conditions of the atmosphere. Among the services which he rendered to medical practice were the treatment of intermittent fever by cinchona and the administration of cooling remedies in smallpox. His works, which are not numerous, were written in Latin, but have been frequently translated. Among them is *Methodus Curandi Febres* (1666; 3d ed., *Observationes Medicae*, 1676). In 1843 was founded the Sydenham Society, for the purpose of printing important medical works in English and other languages. Its first issue was the complete works of Sydenham, in Latin (1846; English trans. by Dr. Greenhill, with a memoir by Dr. Latham, 1848). D. in London, Dec. 29, 1689.

Sydney [named after Thomas Townshend, first Viscount Sydney]: capital and chief port and railway center of New South Wales, Australia, and the oldest city of Australasia; on the southern side of Port Jackson, in lat. 33° 52' S., lon. 151° 12' E. (see map of Australia, ref. 7-J). The climate is temperate and generally healthful. The mean temperature is 62° F., ranging from a minimum of 35° to a maximum of 106°. The mean annual rainfall is 52 inches. Port Jackson is a long, slender inlet on the east coast, of irregular form, with numerous bays and coves, forming a magnificent harbor with a water front of more than 100 miles. The entrance is only a mile wide, but just inside is a bar with only 20 feet of water at low tide, increased by dredging to a few feet more. At the opposite end of the port enters George's river, navigable to Liverpool, a distance of 14 miles.

The city proper is about 4 miles from the heads, on a peninsula between Rushcutter Bay on the E., and Blackwattle Bay on the W. It has a water front of 8 miles, of which 6 are available for the use of commerce. The surface is undulating, with a maximum height of 230 feet. The streets are often crooked and steep, but this gives the city an old-fashioned appearance unique in Australia, and affords frequent and charming vistas over the waters of the bay and to the opposite shores. There are many public parks, including the Domain (130 acres), extending to the water front along the most densely populated and busiest part of the city, and Moore Park (500 acres), to the S. E. of the city. The suburbs are numerous and contain a large population. The more fashionable suburbs are toward the E., while the business portion is extending westward. The entire distance to Parramatta, about 15 miles, is practically suburban along the railway. The manufactories are more on the southern side, and population is rapidly extending toward Botany Bay, 6 miles to the S. There are also considerable suburbs on the north shore of the bay, which are connected with the city by steam-ferries and by rail.

The water-supply was first obtained from the small Tank stream flowing into Sydney Cove, along which the nucleus of the town was first formed. Later it was derived from a stream flowing into Botany Bay, brought to the city by a long tunnel. As this proves insufficient, a plan is under way to bring water from the Nepean river, taken at a point 63 miles distant and conducted to a large storage reservoir near Parramatta. The sewage is conducted to the water front, but as the size of the city renders this unsanitary, a large sewer is under construction to a headland on the ocean shore, where the sewage will be delivered into deep water and carried away by the current from the N.

The public and many private buildings are of fine style and good aspect, and are generally made of a fine sandstone found in the vicinity. The university is the most important edifice in Australia, the principal façade being 500 feet in length. Together with the affiliated colleges of St. Paul's and St. John's, it lies in a domain of 150 acres. With regard to its degrees it has the status of the English universities. The metropolitan cathedral of St. Andrew's and the Roman Catholic Cathedral of St. Mary are two of the finest structures in Australia. The royal branch mint at Sydney issues nearly £3,000,000 worth of coin annually, mostly gold, but with a little silver and bronze. The city is in the center of a large coal-basin, and the beds probably pass under the city itself. Coal is cheap and abundant, and the

commercial advantages are great. The manufactures include all the products of the pastoral industry, and especially boot and shoe making, railway manufactures, carriage and wagon making, manufactures of glass, pottery, furniture, stoves, tobacco, etc., and distilling and brewing. In 1893 1,323 vessels cleared from Sydney, as compared with 1,593 from the other ports of the colony.

The city was founded in 1788 by Capt. Phillip as a penal station, and long remained a humble village. In 1861 it had 56,845 inhabitants, 93,685 with the suburbs. In 1891 the census gave the city and suburbs 383,386 inhabitants, which was 34 per cent. of that of the entire colony. At the end of 1893 the estimated population was 421,030, bringing this city to a point not far behind Melbourne.

MARK W. HARRINGTON.

Sydney: chief port of Cape Breton, Nova Scotia, and capital of Cape Breton County, formerly capital of the province of Cape Breton; on the east side of Sydney Harbor, lat. 46° 18' N., lon. 60° 12' W. (see map of Quebec, etc., ref. 1-D); station on the Intercolonial Railway, 275 miles N. E. of Halifax. The harbor is one of the best in the provinces, but it is ice-bound during the long winter. It is the principal port for the coal-mining district northeast, with which it is connected by rail. The harbor was originally the rendezvous of the Spanish fishing-fleet, and was then called Spanish Bay. Later it was a center for British military activity, and so remained until the Crimean war. France has, by treaty, coaling privileges here, and utilizes them to make this the station of her naval squadron on the North Atlantic. Regular connection is kept up with Newfoundland by steamer in summer. Pop. 4,000.

MARK W. HARRINGTON.

Sydney: See SIDNEY.

Syene: See ASSOUAN.

Syenite: granular crystalline rock, consisting of alkali-feldspars (mostly orthoclase) with some lime-soda-feldspar, one or more ferromagnesian silicate: biotite, amphibole, or pyroxene; and little or no quartz, besides other minerals. According to the kinds of minerals accompanying the alkali-feldspars varieties are distinguished as quartz-syenite, augite-syenite, mica-syenite, hornblende-syenite (syenite proper), zircon-syenite, sodalite-syenite, etc. Its texture varies from coarse-granular to fine-granular, often exhibiting lath-shaped feldspars on the surface of fracture. Occasionally porphyritic, passing into syenite-porphyry and orthoclase-porphyry. With increasing quartz it grades into granite, and with more lime-soda-feldspar it grades into diorite. Varieties low in silica carry nephilite and sodalite, and grade into eleolite-(nephelite)syenite, which properly constitute a separate rock-group. (See Rocks.) This variety is relatively high in soda and potash, which characterize the feldspars and feldspathic minerals, and enter into the ferromagnesian minerals, producing arvedsonite, barkevikite, acmite, ægerite. This rock usually carries rare minerals, containing the rarer elements cerium, lanthanum, thorium, yttrium, etc.

The name syenite was first used by Pliny for the rock from Syene (Assouan) in Egypt. It was subsequently applied by Werner to the rock from the Plauensche Grund, near Dresden, from which it has grown into its present significance. It has been found that the rock from Syene is rich in quartz, and therefore a granite. Until recently the name syenite has been applied to hornblende-granite to distinguish it from mica-granite.

Syenite proper is much less common than granite, and has been identified in comparatively few localities in the U. S. outside of New Hampshire. Eleolite-syenite is somewhat better known, occurring in Arkansas, New Jersey, Maine, and Canada. It is known in Brazil, and especially in Norway, where numerous rare minerals associated with it have been described by Brøgger. See GRANITE.

J. P. IDINGS.

Sykes, GEORGE: soldier; b. at Dover, Del., Oct. 9, 1822; graduated at the U. S. Military Academy in 1842; served in the war with Mexico; was on frontier and garrison duty 1848-61; was in May, 1861, appointed major of the Fourteenth Infantry; commanded the regular troops in the battle of Bull Run; commanded as brigadier-general the regular infantry in the defenses of Washington during the winter of 1861-62, and in the Virginia Peninsular campaign of 1862 the division of regulars (Porter's corps) which so stubbornly maintained its position on the right at the battle of Gaines's Mill. He commanded this division at the second battle of Bull Run; also at Antietam, Fredericksburg, and

Chancellorville, having been promoted major-general of volunteers Nov. 1862, and on the appointment of Gen. Meade to the command of the Army of the Potomac (June, 1863) Sylla succeeded to that of the Fifth Corps, which a week later was engaged at Gettysburg, and at the head of which he continued during the ensuing operations of the Army of the Potomac until Dec., 1863, when ordered to duty in the department of Kansas. He was brevetted colonel for gallantry at Indian's Mill; brigadier-general for Hollysburg, and major-general for gallant services. Mustered out of the volunteer service in Jan., 1866, he returned to duty with the Fifth Infantry, of which regiment he had been appointed lieutenant-colonel in Oct., 1864. In Jan., 1868, he became colonel of the Twentieth Infantry. D. at Fort Brown, Tex., Feb. 9, 1880.

Sylla: See SYLLA.

Syllabus [= *Syllo* Lat., from Gr. συλλαβή, *syllabē*, take together; *syllō*, together + *syllō*, take]; a list of eighty propositions condemned by Pius IX. in his encyclical, *Unigenitus*, and other official utterances. It is annexed to the bull "Quanta Cura," and was published by Cardinal Antonelli Dec. 8, 1864. The errors are grouped under ten heads, and concern pantheism, naturalism, and absolute rationalism; moderate rationalism; religious indifference and latitudinarianism; the unqualified condemnation of socialism, communism, Hindu societies, secret societies, and clerical liberal unions in Italy; the rights of the Church; the rights of the state; natural and supernatural ethics; Christian marriage; the temporal power of the pope; and modern liberalism.

The document is purely negative in form, and states only the propositions to be rejected, but it is very well understood that the contradictory of the condemned propositions is to be held, and not the contrary. Failing to grasp this distinction many have given false and absurd interpretations to the syllabus. So understood, it is evident that the syllabus does not claim for the Church "supreme control" over public education, science, and literature, but merely desires such control to the state (Proposition 45). Among Roman Catholic theologians the specific character and doctrinal value of the syllabus are still a matter of dispute. Some contend that it is infallible, but not *de fide*; others that it is also *de fide*; others that it is simply a list of errors drawn up for convenience of reference for bishops, theologians, etc., each proposition having only that specific kind of assent to it in the syllabus which was put upon it in the original document from which it was drawn. When in 1871 Dr. Schullis, professor at the University of Prague, contended that the syllabus is *de fide*, Dr. Feiler, Bishop of Pilsen in Austria, wrote in refutation a work for which he received a letter of congratulation from Pope Pius. The Church has not decided that all the propositions in the syllabus are heretical (but only that they are to be rejected); therefore it does not follow that the contradictory propositions are all so many articles of faith. The Roman Catholic Church is accustomed to condemn some propositions as heretical, others as erroneous, others as rash, others as injurious, others as dangerous, others as scandalous, others as offensive, others again as merely historically false. So, too, each proposition in the syllabus deserves some censure, but not necessarily the worst—viz., of heresy. Some propositions in the syllabus do not refer to doctrine at all, but only to matters of fact—viz., propositions 12, 23, 34, 38, 72. See Cardinal Hergenrother's *Catholic Church and Christian State*; Gladstone's *Vatican Decrees*, and the replies of Cardinals Newman and Manning; also Gladstone's rejoinder, entitled *Vaticanism*. The text of the syllabus is found in the *Acta et Decreta Concilii Vaticani*, Berol. (Freiburg im Breisgau, 1871).

JOHN J. KEASE.

Syllologism: See LOGIC.

Sylvanite: See TELLURIDES.

Sylvester: the name of two popes and an antipope. St. Sylvester I. (314-335) governed the Church during the reign of Constantine I. The basilicas of the Lateran, St. Peter, St. Paul, the Sessorian basilica, and many churches were completed under his pontificate. Much of the ancient Church legislation is referred to him. The original documents for his life are not extant. It is no longer maintained that he baptized Constantine, or that the latter's donation to Sylvester is genuine. Nevertheless he awarded much influence over the emperor, and received from him many gifts of land and church plate. (See Duchesne, *Liber Pontificalis*, pp. 176, 187; Hergenrother, *Church and State*, p. 657.)—SYLVESTER II., whose true name was GERHARD, was born in Acconia; studied in Spain under Bishop Hatto of Lyons, and with the Arabs at Seville and Cordova; traveled in Italy; acquired a great reputation for learning, and was appointed by Otto II. teacher to his son, Otto III. While director of the school of Rheims, to which he attracted many students, he was elected archbishop of that diocese in 991 by a synod which deposed Archbishop Arnulf, but he was not confirmed by the pope, and had to give up his see to Arnulf. He then left Rheims, and repaired to Otto III., by whose aid he became Archbishop of Reims in 996, and in the following year pope. His knowledge of mathematics, astronomy, and physics led people to consider him a magician, and it was a popular rumour (see Dehlinger's *Fables respecting the Popes in the Middle Ages*, Eng. trans., pp. 267-272) that he had sold his soul to Satan.—SYLVESTER III. was for three months the antipope of Boniface IX. and Gregory XI., and was deposed by the Synod of 1046.

Revised by J. J. KEASE.

Sylvester, James Joseph, F.R.S., F.R.C.L., F.R.S., [mathematician] b. in London, Sept. 8, 1814; studied at Cambridge, but could not take a degree on account of being a Jew; became Professor of Natural Philosophy at University College, London; went to the U. S. in 1841, and was in 1841-42 a professor in the University of Virginia. He soon returned to England, and in 1855 became Professor of Mathematics at the Military Academy at Woolwich. In 1856 he was invited to the chair of Mathematics in the Johns Hopkins University, where he remained until 1883. He then returned to England as Savilian Professor of Geometry at the University of Oxford. He is the most prolific and original of living mathematicians. He has written hundreds of memoirs in the *Transactions of the Royal Society*, *Proceedings of the London Mathematical Society*, *Crelle's Journal*, *Quarterly Journal of Mathematics*, *Comptes Rendus*, and many other journals, and in *The American Journal of Mathematics*, of which he was the founder. He enumerated a theory of verification in a volume, *Logic of Verse* (London, 1870), and has invented several kinematic instruments. N. N.

Sylvester, Junius; author; b. in England in 1583; became eminent as a linguist; was a member of the Company of Merchant Adventurers at Stade, Holland. D. at Middelburg, Holland, Sept. 28, 1618. He is best known as the translator into English of Du Bartas's *Divine Weeks and Works* (1606; 7th ed. 1641). The original was by a French Huguenot nobleman; Sylvester's version had great popularity among the Puritans of Old and New England, and was one of the sources of inspiration to Milton when writing *Paradise Lost*. The quaint "venerable" style of Du Bartas was, if anything, exaggerated in the translation. In 1615 Sylvester published a singular anti-Jewish tract—*Pharoah's Hithered and the Pope's Shattered, etc.*—intended to please James I., who hated the Jew.

H. A. DREES.

Sylvian'idea: an earlier name for the *Mandibula*. See WARRLER.

Sylviculture: See FORESTRY.

Sylv'ide: See WARRLER.

Syl'vius, JACQUES (JACQUES DYBINE); anatomist; b. at Louville, near Amiens, France, in 1478; studied medicine at the University of Paris, where he was appointed professor in 1530. He was the first to practice injection of the blood vessels during their dissection; a fissure of the cerebrum is called the fissure of Sylvius. D. in Paris, Jan. 10, 1555. His *Opera Medica* were collected by René Moreau, and appeared at Geneva in 1630.

Symbiosis [Gr. *syllō*, companionship; cf. *syllabē*, partner; *syllō*, with + *bios*, life]; a kind of COMMENSALISM (q. v.), in which the associated forms are intimately associated with and dependent upon each other. Thus the plants known as lichens are composed of symbiotic associations of algae and fungi. The association of "yellow cells" (plants) in the *Radiolaria* (animals) is an example in the animal kingdom. J. & K.

Symbolic Logic, or, better, **Algorithmic Logic;** a form of logic characterized by an artificial language composed of symbols with their laws of combination, and possessed of peculiar advantages in giving of actual relations representations which can be manipulated according to rules of operation and procedure, experimented upon to give new knowledge according to organized processes.

Before George Boole logic always dealt with its materials

directly and by intuitive perception, as did the old Greek geometry. What Descartes's analytic geometry did for the science of space, that Boole's algebra did for logic. His discoveries, startling as they appear, yet rest upon a principle well known to the modern mathematician. Though he had noteworthy forerunners, algorithmic logic, as a practical system, owes its creation wholly to his genius. He was, in a sense, the outcome of his time, the period when algebra was given a real plural. His discoveries in the algebra of linear substitutions are regarded as the foundation of the present vast theory of invariants. His *General Method in Analysis*, discovered in his researches on differential equations, reads like a prelude to his *Symbolic Logic*. His remarkable pamphlet, entitled *The Mathematical Analysis of Logic, being an Essay towards a Calculus of Deductive Reasoning*, by a curious coincidence made its appearance on the very same day as De Morgan's *Formal Logic*. In this he shows that by simply assuming 1 to signify what is, and 0 what is not, he can, without any further assumption, express the premises of a syllogism as two equations from which, by ordinary algebraic procedure, the conclusion can be deduced. This is a pregnant connecting of the concepts of being and nothing with a number system. Still more profound and unexpected is his developing a function of a general logical symbol by Maclaurin's theorem:

$$\phi(x) = \phi(0) + \phi'(0)x + \frac{\phi''(0)}{1.2}x^2 + \text{etc.}$$

Thus at a touch Boole changed a dead into a living science. Moreover, to the old synthetic logic he added a new analytic logic, namely, that the validity of the processes of an algebra does not depend upon the interpretation of the symbols which are employed, but solely upon the laws of their combination. Every system of interpretation which does not affect the formal operational laws is equally admissible, and so the same piece of symbolic algebra may, under one scheme of interpretation, represent the solution of a question on the properties of numbers, under another that of a geometric problem, under a third that of a problem of kinematics, under a fourth that of a new question in logic.

This principle, so fundamental that Boole assigns it as the definitive characteristic of a true calculus or algebra, may be illustrated as follows: If we define a sect as the piece of a straight between two definite points; if we indicate sects by the symbols x, y, z , etc.; if we define the product of two sects, xy , as the rectangle of those sects (not the area of the rectangle of the sects, but the surface of the rectangle determined by them); if we define the product of three sects, xyz , as the cuboid of those sects (not the volume of that cuboid), then all the theorems of Euclid's Book II. are rigorously demonstrated by the little equations usually appended to the propositions as mere numerical illustrations (e. g. in Playfair); and that, too, without any introduction of the idea of measurement or ratio. Moreover, each proposition may at once be generalized for space of three dimensions, and the mere algebraic statement of the generalization will contain its rigorous demonstration.

This general principle likewise explains why a professional mathematician in working out a way of accurately expressing by an algebra the operations and valid processes by which reasoning is ordinarily performed should make it as similar as possible to the ordinary algebra for number; not because thinking in its general character has any reference to number, but simply to get the benefit of as many as possible of the results and procedures produced by centuries of algebraic advance.

The aim of Boole's investigations was, in the first instance, confined to the expression of the antique logic, and to the forms of the Aristotelian arrangement, but he soon found that restrictions were thus introduced which were purely arbitrary and had no foundation in the nature of things. Feeling with the instinct of genius the high importance of his work, Boole applied his best powers to an elaboration, which appeared in 1854 under the title *An Investigation of the Laws of Thought on which are Founded the Mathematical Theories of Logic and Probabilities*, a work of which Herbert Spencer has said that it "constitutes a step far greater in originality and importance than any taken since Aristotle." The following is a summary of Boole's actual working method:

Convene to represent any class by a letter, as men by a and good things by b . Combined in thought one acts as a selective adjective, and whichever this be the result is the same; so that ba , or "good men," gives us the same collec-

tion of individuals as ab , or "human good beings." Using the sign $=$ as meaning, in the most general way, identity, co-existence, or equality, we say $ab = ba$. "We are permitted, therefore, to employ the symbols x, y, a, b , etc., in the place of substantives, adjectives, and descriptive phrases, subject to the rule of interpretation that any expression in which several of these symbols are written together shall represent all the objects or individuals to which their several meanings are together applicable, and to the law that the order in which the symbols succeed each other is indifferent." Again, to form the aggregate conception of a group of objects consisting of partial groups, we use the conjunctions "and," "or." Convening that the classes so joined are quite distinct, so that no individual is added to himself, we see that these conjunctions hold precisely the same position formally as the sign $+$ in algebra, and are representable by that sign.

As the order of addition is indifferent, we have $x + y = y + x$. Again, to separate a part from a whole, we express in common language by the word "except," as "All men, except Asiatics."

This is our minus sign. As it is indifferent whether we express excepted cases first or last, we have $x - y = -y + x$.

But just as the algebra of quaternions differs in one fundamental law from the algebra of number, namely, in its multiplication being non-commutative, so that ab does not equal ba , so Boole's algebra for logic differs in a law equally fundamental: in it $a^2 = a$; and from this comes the fact that, in it, every equation can be solved and every solution interpreted. Only two symbols of number obey this formal law. They are 0 and 1. Their interpretation for logic is *nothing* and *universe*, the two limits of class-extension. This law $x^2 = x$ it is which in Boole's algebra makes division indeterminate: but his genius overcomes this indefinitude by his expansion theorem. For example, from the proposition "All men are all the rational animals," $m = ra$, what can we get about animals? By developing, $a = \frac{m}{r} = f(m, r)$

$= f(1, 1) m.r + f(1, 0) m.r' + f(0, 1) m'r + f(0, 0) m'r'$. Hence all animals consist of all men and some irrational things (r') not men (m').

If we would use trial references to the premises the coefficients of the expansion are no longer needed, and by making these trial references mechanical we have from Boole's one theorem the interesting logical machines of Jevons and Marquand. In the latter, the premises being reduced to the form of the combinations to be excluded, as suggested by Boole, the operation of excluding these combinations is performed mechanically by the machine, and the conclusion exhibited. Boole's wonderful creation was so strange that it germinated slowly.

In 1864 Jevons began using $+$ to unite different terms into one aggregate, whether they be mutually exclusive or not. McColl and C. S. Pierce gave slightly varying algebras, adding a new sign to express *existence*. In 1877 Ernst Schröder, in his *Operationskreis des Logikkalküls*, gave a beautiful simplification of the Boolean calculus, in which appears a duality like that of modern synthetic geometry. In 1879 Dr. Alexander Macfarlane published an algebra of logic which is particularly powerful for handling questions of probable inference and relationship.

Leslie Ellis, De Morgan, Joseph John Murphy, Alexander Macfarlane, and particularly C. S. Pierce, have developed a highly interesting symbolic logic of relatives. Prof. Peano, of Turin, is publishing a formulary containing the known propositions of the various subjects of mathematics, all written in a general symbolic language formed on the basis of algorithmic logic.

Finally, Dr. Ernst Schröder has collected in two encyclopædic volumes a systematic and critical account of all that makes the present status of algorithmic logic, including his own exceedingly important developments of many essential parts. In the first volume of this great work, *Vorlesungen über die Algebra der Logik (exakte Logik)* (first vol., Leipzig, 1890), the logical operations called identical multiplication and addition are shown to deserve these names, since all laws of addition and multiplication in general arithmetic which hold as general formulas, that is, without reference to the nature or individuality of the combined numbers, hold also for these logical operations; while the inverse operations may always be replaced by a simpler operation, *negation*, which appears as a common special case of each. The method of using the logical calculus is thus surprisingly simplified.

GEORGE BRUCE HALSTED.

Symbols, in zoölogy: See ZOOLOGY.

Symbols, Chemical: See CHEMISTRY.

Syme, JAMES, M. D.: surgeon; b. in Edinburgh, Scotland, Nov. 7, 1799; graduated in surgery 1821; was lecturer and Professor of Surgery at Edinburgh many years, and originated many improvements, including the resection of diseased joints in place of amputation, the process known as Syme's operation for amputation of the foot at the ankle-joint, and the removal of large tumors of the lower jaw by excision of the entire bone. He was the author of *The Excision of Diseased Joints* (1831) and *Principles of Surgery* (1832), both reprinted at Philadelphia (1866). D. in Edinburgh, June 26, 1870. See the *Memorial* by Dr. Robert Patterson (Edinburgh, 1874).

Symmachus (Gr. Σύμμαχος): one of the three chief translators of the Old Testament into Greek who attempted to improve upon the LXX. Fragments of his translation have been preserved in that which remains of the *Hexapla* of Origen. According to Epiphanius (*De Mens. et Pond.* 16), he was a Samaritan living at the time of Severus (193-211). Eusebius (*Hist. Eccl.* 6, 17) and Jerome (*Opp.* ii., p. 894) say that he was an Ebionite. (Cf. also Nestle, *Theol. Stud. und Krit.*, 1879, p. 733.) Geiger (*Jüd. Zeitschr.* i., p. 62) tried to prove that he was a Jew. He must have lived later than Ireneus, who in 180 A. D. (*Adv. Hær.*, 3, 24) does not mention him. Symmachus translated freely, and attempted to write a polished Greek. See also Field, *Hexapla*, i., chap. iii.; Bleek-Wellhausen, *Einführung*, p. 582; F. Buhl, *Kanon des Alt. Test.* (Leipzig, 1891, § 54).

RICHARD GOTTHEIL.

Symmachus: pope (498-514); a Sardinian by birth; consecrated Nov. 22, 498, after the death of Anastasius II., but his election was contested, and Laurentius was on the same day made antipope. Symmachus was supported by Theodoric, King of Italy, and Laurentius by the Byzantine emperor. The contest lasted about seven years, but was decided in favor of Symmachus. Of more interest are the enactments of the synods which were held during his reign, and which contributed much to the systematic organization of the papal administration. Some seven councils were held (499-504) in which the election of the pope was regulated, the free disposition of Church goods forbidden to laymen and made more difficult even for the clergy, the principle proclaimed that the occupant of the Roman see could be judged by no inferior, etc. He was distinguished for his zeal in building and restoring churches, in redeeming captives, and aiding the needy. D. July 19, 514. See Duchesne, *Liber Pontificalis*, i., p. cxxiii., 260. JOHN J. KEANE.

Symmachus, QUINTUS AURELIUS: author and orator; b. about 350 A. D.; educated in Gaul; held some of the highest civil offices in Rome in the latter part of the fourth century A. D. Of his works, the *Epistolarum Libri X.* are extant, and are of considerable historical interest; editions by Juretus (1580), Scioippius (1608), and Pareus (1651). Fragments of his speeches were discovered by Cardinal Mai, and published in *Scriptorum Veterum nova Collectio* (1815) and in Meyer, *Orat. Rom. Fragm.*, pp. 627-636. The best edition of all the works is by O. Seeck (Berlin, 1883); smaller edition by Kroll (Leipzig, 1893). Symmachus was one of the last champions of paganism, and a noble and pure character. D. about 405 A. D. Revised by M. WARREN.

Symonds, JOHN ADDINGTON: critic, biographer, and literary historian; b. at Bristol, England, Oct. 5, 1840; educated at Harrow School and Balliol College, Oxford, where he took the Newdigate prize; was elected a fellow of Magdalen in 1862. Ill health necessitated his residence for several years at Davos-Platz, Switzerland. Among his writings are *An Introduction to the Study of Dante* (1872); *Studies of the Greek Poets* (1873-76); *Sketches in Italy and Greece* (1874); an exhaustive work in seven volumes on *The Renaissance in Italy* (1875-86); *Sketches and Studies in Italy* (1879); *Essays* (1890); *In the Key of Blue* (1893); *Shakespeare's Predecessors* (1884); *Walt Whitman* (1893); besides several volumes of verse, original and translated, lives of Shelley, Michelangelo, Ben Jonson, and Sir Philip Sidney, and a translation of the *Autobiography of Benvenuto Cellini* (1887). D. in Rome, Italy, Apr. 19, 1893. H. A. BEERS.

Symons, GEORGE JAMES, F. R. S.: meteorologist; b. in London, England, Aug. 6, 1838; educated by private tutors. From 1860 to 1864 he was assistant to Admiral Fitzroy in the British Meteorological Office. In 1860 he established the annual publication entitled *British Rainfall*, and in

1865 the monthly called *Symons's Meteorological Magazine*, both of which he still conducts (1895). He established a rainfall service of his own, and this now extends over the British islands. He was chairman of the Krakatoa committee of the Royal Society (1884), and editor of their *Report*. MARK W. HARRINGTON.

Sympathy [from Gr. *συμπάθεια*, community of feeling, deriv. of *συμπαθής*, affected by like feelings; *σύν*, together + *πάθος*, feeling]: the emotion aroused by any presentation which suggests suffering or pleasure.

1. It is aroused by states clearly pleasurable or painful. There is no occasion for sympathy with one who does not need it; that is, with one who is not in a state of positive feeling, good or bad. Further, the study of the first sympathies of children shows that they extend to things as well as to persons, and only gradually get narrowed down to objects which feel. Sympathy as an emotion is shown before the child makes any distinction between things that feel and those that do not. But whatever the object be, the emotion is called forth only by such happenings as have before excited the child's own feelings of pleasure or pain.

2. Some degree of interest is necessary to sympathy. The confirmation of this appears broadly in everyday experience. For example, a man reads in the morning paper that thousands of people perish in a Chinese flood, and the cup of coffee that follows it up is much more important to him than their bereaved families; but a single death in his own community makes him at once solicitous in reference to the deceased man's relatives. Yet mere exploring interest when it comes upon suffering always starts the sympathetic feelings.

3. A person's sympathy is in a rough way proportionate to the nearness of the individual's connection with himself. This, again, needs no detailed proof; if one's brother breaks his leg one feels more sympathy than if a casual comrade meets the same misfortune; and the difference is greater still if the latter be only an animal, as, for instance, a favorite horse.

4. Sympathy is aroused, not merely by real beings, but by any idea of suffering. It is not necessary that one believe in the object of one's sympathies. Pictures in memory win sympathy, imaginations in fiction arouse it, vague forebodings of misfortune to others excite it. Whenever there arises in consciousness an idea of a conscious creature—be he fact, memory, fancy, illusion, reality in any of its kinds, that is, be he a possibility in any form—his fortune as suffering or enjoying moves our sympathy. This is true in spite of our efforts—often successful as they are—to suppress sympathetic emotion by dwelling upon the unreality or ill desert of the subject of it. *Little Dorrit* will move some readers in spite of their sense that the character is fictitious. We all feel the stirrings of fellow-feeling for the condemned criminal, even though we be convinced of the justice of his sentence. In cases in which we do suppress the emotion it is by getting rid of the idea, turning the attention to something else, exciting some new interest, that we do it; not by depriving the subject in question, the idea of suffering, of its force to affect us.

In this definition several further considerations are involved. By the use of the word "suggestion" an important distinction is intended between the object on which sympathy terminates and that by which it is caused. A suggestion is a stimulating idea which is brought into consciousness from without, or comes by an association, in such a way that it does not belong in the course of my real life. A suggested pain, for example, is a pain which a person is led to think of, but which he is not really suffering. Suggested suffering, therefore, is the idea of pain as far as it differs in consciousness from the actual pain of the experience presented.

But the question arises: Does such a suggestion excite sympathy? Suppose a cruel father who punishes his child by pinching, the presentation of the father may suggest pain to the child; but this does not seem to be sympathy—it may be fear, or memory of pain. Yet, on looking closer and observing children, we find that if the father take the attitude which the pain before accompanied, real sympathy is excited. Let him pinch a piece of wood, paper, even his own finger, and the child a year old gives clear expression to its sympathetic emotion. The child does not need the notion of another person who suffers, nor even of another object that suffers; he only needs two things: first, a presentation which suggests vivid pain, and second, the ab-

sence of the coefficient of reality which his own suffering had. In other words, the emotion of sympathy does not require an object at all. It acquires an object, and then maintains itself by the emphasis of this object; but in the first place it attaches to any convenient presentation in close connection with its exciting cause.

Kinds of Sympathetic Suggestion.—We may sympathize, therefore, without sympathizing with anything, and at first this is the experience of the young child. But its sympathy gets an object, and so maintains and develops itself. The child inherits a susceptibility to a social response to others' actions, and also by imitating their expressions he learns how similar organic conditions feel.

Altruistic Element in Sympathy.—The much discussed question of egoism versus altruism in the sympathetic emotion may receive partial consideration here. If it be true that suggested suffering excites sympathy, and that it is only suggested suffering that excites it, namely, suffering not present as real suffering is, and for that reason attributed, when knowledge is sufficiently advanced, to some one else—then we must believe that sympathy is not entirely egoistic. Suggested suffering is at first neither egoistic nor altruistic, because neither the ego nor the alter exists in consciousness when sympathy at first arises. The reference of real pain to self, and of suggested pain to another, seem to be both late acquisitions. But as it is true that the child gets his external objects clearly presented—especially his external personal objects—before he clearly presents himself, so sympathy must be a conscious emotional motive before self-seeking is.

Varieties of Sympathetic Emotion.—A large number of varieties or shades of emotion may be classed as sympathetic, i. e. kindness, benevolence, charitableness, etc. When felt toward an equal in character or station, we call it congratulation, fellow-feeling, fellow-suffering, companionship, common well or ill desert, solicitude, heartache; toward an inferior, compassion, pity, mercy; toward one much superior, it approaches awe, but differs from it in an unnamable way. J. MARK BALDWIN.

Sym'phony, or Sinfonia [*symphony* is viâ O. Fr. and Lat., from Gr. *συμφωνία*, a chording, unison, symphony, deriv. of *σύνφωνος*, harmonious, chording; *σύν*, with + *φωνή*, sound, voice. *Sinfonia* = Ital. < Lat. *symphonia* = Gr.]: in music, an elaborate composition designed for performance by a full orchestra, and consisting of several distinct movements (usually four in number), each of which has its own individual character, as the *allegro*, *andante*, *adagio*, *minuet*, *scherzo*, etc., while the whole unite in forming one symmetrical and complete work of art. There appears to have been no important difference between the symphony and the overture until about the end of the eighteenth century. Revised by DUDLEY BRUCK.

Sympho'sius: a Latin writer of the fourth or fifth century, about whom nothing definite is known. A collection of 100 riddles, each in three hexameters, is extant under his name. See Bachren's *Poet. Lat. Minores*, vol. iv., pp. 364-385, and Corpet's *Enigmes de Symposius recues sur plusieurs manuscrits et traduits* (Paris, 1868). M. W.

Sym'phyla [Mod. Lat., from Gr. *σύνφυλος*, of the same stock; *σύν*, together + *φυλή*, tribe]: in entomology, the group containing the peculiar myriapod *Scolopendrella*. The name was given under the impression that it united the characters of the MYRIAPODA and THYSANURA (qq. v.). *Scolopendrella* is really an aberrant diplopod, and has no other affinities. J. S. K.

Symphytum: See COMFREY.

Symplesom'eter [Gr. *συμπλέσις*, compression (deriv. of *συνπίεσις*; *σύν*, together + *πίεσις*, press) + *μέτρον*, measure]: an instrument for indicating the amount and variations of atmospheric pressure, consisting of a vertical glass tube, terminated above by an oblong bulb, and bent upward at its lower extremity, where it expands into a cistern open at the top. The bulb and upper part of the tube contain hydrogen, the cistern and lower part of the tube colored oil of almond. As the pressure of the atmosphere varies, the inclosed hydrogen expands or contracts by proportional but large quantities, and the liquid consequently rises or falls in the tube through large spaces; the scale attached is corrected also for temperature, and its indications correspond to those of a mercurial barometer.

Symplegades, sim-pleg aā-dēz, or Cya'nean Rocks (anc. *Συμπληγάδες* or *Κυανέαι*): two small islands at the Black Sea

mouth of the Bosphorus, on opposite sides of the strait: famous in mythology. When any living thing was passing between them they were supposed to come together immediately and then separate. Jason with the Argo by a stratagem eluded their collision, and they have since been immovable. That on the Asiatic side has disintegrated and almost entirely disappeared. That on the European side is about 550 feet long and 70 wide, consisting of three masses of volcanic rock. On its highest point is a marble pedestal with the inscription "Divo Casari Augusto." E. A. GROSVENOR.

Symptoms [from Mod. Lat. *symp'to'ma*, symptom, from Gr. *σύμπτωμα*, mischance, casualty, symptom, deriv. of *συνπίπτειν*, fall in with, meet with; *σύν*, with + *πίπτειν* (perf. *πέπτωκα*), fall]: in medical diagnosis and prognosis, the phenomena by which the physician judges of the nature and probable course of the disease he deals with. Symptoms are *objective*, that is, perceptible to the physician's senses, or *subjective*, perceptible only to the patient's senses, such as pain, deafness, etc. Each may be valuable, but the former are, as a rule, much more to be depended upon. These are by some writers called *physical signs*, as distinguished from *vital symptoms*, but these are sometimes objective, and practically all are classed as symptoms. Few symptoms are absolutely *pathognomonic*, or infallible signs of some one disease; but in general the import of symptoms can be learned only by the use of careful observation and patient and logical thought, guided by experience. In early times, when the knowledge of diseases was less advanced than at present, certain symptoms were regarded as diseases. Thus dropsy, asthma, diarrhoea, and the like have passed from their position as diseases to their proper station as mere symptoms of various and often quite dissimilar affections. It is still necessary to regard certain symptoms as diseases, particularly in the case of the nervous system, but advancing knowledge makes these fewer and fewer. WILLIAM PEPPER.

Synæresis: See SYNIZESIS.

Syn'agogue [= Fr. < Lat. *synagoga*, from Gr. *συναγωγή*, a bringing together, collecting, (in Septuagint and New Testament) assembly, synagogue; *σύν*, together + *άγω*, lead. The Hebrew name was *Keneseth* or *Beth Hakkene'seth*: Aram. *Kenishtë*. Other Greek names are *συναγωγή*, *προσευχή*, *προσευκτήριον*, *σαββατεῖον*]: a congregation or assembly of Jews met for the purposes of religious instruction and worship; also the building devoted to such purposes.

Origin.—It is impossible to fix with any accuracy the date at which the synagogue took its rise. Despite rabbinical traditions, its beginnings probably do not go beyond the Babylonian captivity. Far away from the national religious center, prayer became for the Jews a substitute for sacrifice, and a study of the traditional literature a religious exercise. Upon its return to Palestine the new community regarded the Law as an end in itself, and a knowledge of its contents of supreme importance (Josephus, *Contra Apion.*, ii., 17). The first synagogues were established for the reading and study of the Law, and Philo distinctly calls them *διδασκαλεῖα* (*Vita Mosii*, iii., 27). It is thought by some that Psalm lxxiv. 8 has reference to such assemblies. In the New Testament the synagogue is already a fixed institution (Matt. iv. 23, Luke iv. 15, etc.).

Development.—Side by side with the temple numerous synagogues were established in Jerusalem. Acts vi. 9 mentions those of the Libertines (freedmen), Cyrenians, Alexandrians, Cilicians, and Asiatics. They seem to have spread over the whole of Palestine. Ruins of synagogues have been found in Galilee, in Kasium, Kefr Birim, El-Jish, Meiron, Nabartein, Kedes, Tell-Hum, Keraze, and Irtik. Judging from the architectural remains, these belong to the time between the first and fourth centuries of our era. According to rabbinical law, ten men are sufficient to form a congregation. But also in the Diaspora, wherever the Jews went, they built synagogues (Philo, *De Septenariis*, chap. vi). In Alexandria there were a number (Philo, *Legit. ad Caium*, § 20). Inscriptions found in Rome tell us of nine different synagogues in the city (Berliner, *Gesch. der Juden in Rom*, 1893, p. 62).

Form and Constitution.—According to express rabbinical law, the synagogue was always to be built on the highest point of the city, though there are traces of some which must have been built outside the limits of the city or village. Some services (as on fast-days) were held in the open market-place. The style of the early synagogues is largely

Græco-Roman. In Palestine they were built with the entrance (front) at the S. They were given into the charge of a body of elders who in Palestine—at least in the smaller places—were also the political heads of the community. In places of mixed population and in the Diaspora a special body (*συναγωγή*) was appointed for that purpose, the head of which was called *ῥητορεύς*. To this body was also delegated the power of hurling the ban. For the reading of the service there were no stated functionaries, though throughout the Roman empire we find the *ῥητορεύς* (*Rosh Hakkeneseth*), who watched in general over the service and selected the readers and preachers for each office. As collections for charity were regularly made, there were specially appointed almoners (*gabbā' tzedākāh*). The beadle (*Chazzan Hakkeneseth*, *ῥητορεύς*) had charge of the building.

Service.—The most important object in the synagogue was the Ark (*Tēbhāh*), which contained the scrolls of the law, wrapped in linen and deposited in boxes (*ῥητορεύς*). The readers and preachers officiated from a raised platform (*Bēma*). On New Year's day and on fast-days horns were blown (*Shoferōth*, *Chatzōtzerōth*). The congregation was seated according to a certain order of precedence. The service, which was in Hebrew (though in the Diaspora Greek seems also to have been used), consisted originally of the recitation of the *Shema* (Deut. vi. 4-9, to which xi. 13-21, Numb. xv. 37-41 were added later); the reading of the Law (*Tōrah*), which was done by at least seven men, in a three-year (later on in a yearly) cycle; a reading from the Prophets or Hagiographa (*Hafārāh*); and the priestly blessing. The portions from the *Tōrah* and *Hafārāh* were also translated aloud into Aramaean by a specially appointed officer (*Meturgēman*). Gradually other prayers were added; the first and last three of the so-called *Eighteen Benedictions* have their origin in the times of the Mishnāh. Expositions of the weekly *Tōrah* readings were given by one prominent teacher present (*Shabbatay de raiš*, *Shabbatay de raiš*, Matt. iv. 23), from which the Christian sermon and the Jewish MIDRASH (q. v.) were evolved. The one who was invited to act as reader was called "Messenger of the Congregation" (*Sheliach Tsibbūr*). Services were also held on Saturday afternoon, and on the mornings of Tuesday and Thursday, the chief market-days of the week. It will be seen how closely the organization of the early church followed that of the synagogue.

Further Development.—The building of new synagogues in the Roman empire, though technically illegal, was persistently carried on, and every community of Jews had one or more. During the Middle Ages the synagogue was used as a treasury and as a refuge-place from impending death (Stobbe, *Die Juden in Deutschland*, p. 168). The services grew in number. Minor local festivals were added; the old ones (the Day of Atonement excepted) being celebrated in all places outside of Palestine for two days instead of one. The ritual was developed by the addition of Psalms and of poetical compositions. (See JEWISH LITERATURE—*Characteristics of Hebrew Poetry*.) The best of the Jewish poets of Spain (1030-1230 A. D.) worked in the liturgy of the synagogue. Though the framework of the liturgy, the prayer *par excellence*, remained the same, each country, and almost each city, had its peculiar additions (*Minhag* = custom, rite). It is customary to distinguish two chief rites, the Spanish-Portuguese and the Polish-German; though there are special African, Arabian, Italian, Greek, Spanish, Provençal, German, etc., rituals. The old custom of preaching on every Sabbath gradually fell into disuse. It was relegated to the afternoon service or confined to festivals and special occasions. The rabbi became more of a teacher than a minister, so that by his side there grew up the *Mōchiach* and *Maggid*, the moral preachers. The *Chazzan* developed into the reader and intoned the service. Women were rigidly separated from men. The reform movement in the Jewish Church, which began with Moses Mendelssohn, chiefly concerned the synagogue. His translation of the Pentateuch into literary German (1783) induced the desire for the translation of the prayers into the vernacular. These had grown to intolerable lengths; and, owing to the protracted misfortunes of the Jews, the whole service had become somewhat ungraceful and uncouth. With a view to remedying these evils, the Reform congregations in Berlin and England have modified the synagogue service to some degree, and have in a few synagogues introduced hymn-books in the vernacular, though nearly all the synagogues in Europe and a large number of orthodox and

conservative ones in the U. S. still hold to the old ritual. In the U. S., where the congregational system has been carried to its furthest extent among the Jews, the advanced Reform synagogues have largely curtailed the ritual, have introduced many English prayers, have laid aside the hat and the praying-scarf (*Talit*), have emphasized the importance of the sermon, and administer the rite of confirmation to both boys and girls, which was first introduced in Berlin in 1817. A number of these synagogues have also added to the Friday evening and Saturday morning services a short service and lecture on Sunday morning.

LITERATURE.—See especially Schürer, *Gesch. des Jüd. Volkes im Zeitalt. Jesu Christi*, ii., § 27 (Eng. trans. div. ii., vol. ii.), where the older literature will be found. Cf. also Stapfer, *Palestine in the Time of Christ* (New York, 1885, p. 333); C. G. Montefiore, *The Hibbert Lectures* (1892, p. 388); Herzfeld, *Geschichte des Volkes Israel* (iii., pp. 129, 183); Zunz, *Die Gottesdienstlichen Vorträge der Juden* (2d ed. 1892); Zunz, *Die Ritus des synagogalen Gottesdienstes* (Berlin, 1859); Löw, *Der Synagogale Ritus* (*Mntsch. für Gesch. und Wissen. des Judenth.* (1884); Hamburger, *Real-Encyclopädie für Bibel und Talmud* (part ii., 1883, s. v. *Synagogue*); Holdheim, *Gesch. der Jüd. Reformgemeinde* (Berlin, 1857).

THE GREAT SYNAGOGUE (*Kenēseth Haggēdōlāh*) was an assemblage of 120 men which, according to Jewish tradition, Nehemiah brought together for the reorganization of religious worship and the maintaining of civil order. They are supposed to fill up the gap between the last of the prophets and the first of the rabbis. To this body are ascribed the reconstitution of public worship, the final collection of the canon of the Old Testament, and the introduction of certain prayers. Many other ordinances are referred to their initiative. Richard Simon (*Histoire Crit. du Vieux Test.*, i., chap. viii.) was the first to question the authenticity of this tradition. Abraham Kuenen's treatise on the subject seems to have removed all doubts that we have here simply a myth based upon the assembly of the people mentioned in Nehemiah viii.-x., which solemnly accepted the Law, and that there never existed a legal or religious body known as the Great Synagogue.

LITERATURE.—Kuenen, *Over de mannen der groote Synagoge* (*Verslag en Meded. der Kon. Akademie*, Amsterdam, 1876; trans. by K. Budde in *Gesamm. Abhandl. von A. Kuenen* (Freiburg, 1894), p. 125); Zunz, *Gottesdienstl. Vorträge* (2d ed., p. 34); Grätz, *Die Grosse Versammlung* (*Mntsch. für Gesch. und Wissensch. des Judenth.*, 1857, p. 81); D. Hoffmann, *Ueber die Männer der grossen Versammlung* (*Mag. für Wissensch. des Judenth.*, 1883, p. 45); Ginsburg, *Killo's Cyclopædia s. v.*; Schürer, *Gesch. des Jüd. Volkes* (ii., p. 291); Bleek-Wellhausen, *Einleitung in das Alte Testament* (4th ed., p. 558); Buhl, *Kanon und Text des Alte Testament* (Leipzig, 1891, § 9); Ed. König, *Einleitung in das Alte Testament* (1893, p. 445).

RICHARD GOTTHEIL.

Synap'ta [from Gr. *συνάπτεσθαι*, joined together, fastened]: a genus of HOLOTHURIANS (q. v.), embracing worm-like transparent forms noticeable for the anchor-like plates in the skin, which are favorite objects with microscopists.

Synaptase: See EMULSIN.

Syncope [from Lat. *syn'cope* = Gr. *σύνκοπή*, syncope (in med. and in gram.): *σύν*, together + *κόπτειν*, strike, cut]: in music, a certain arrangement of notes which often produces a sudden check of the rhythmical movement, thus disturbing the regular accent, and rendering emphatic that part of a bar or measure which would otherwise be unaccented. See *a*, *b*, and *c* in the example following:

Syncope of a simpler kind occurs when the last note of any bar and the first note of the bar succeeding are tied together by a "bind," and thus form in reality only one note. Formerly, instead of writing two notes separately with a bind, it was usual to write only one (equal to the sum of both), and place it directly across the bar-stroke.

Revised by DUDLEY BUCK.

Syncope [Gr. *σύνκοπή*, deriv. of *σύνκοπτειν*, chop up, squeeze together; *σύν*, together + *κόπτειν*, chop]: the shortening of a word by a syllable through the omission of a

medial vowel or a medial vowel and one or more consonants. This is the strictest and proper meaning of the term, but it is sometimes loosely applied also to the omission of a medial consonant. Examples of syncope are *hemp* for O. Eng. *henep*, *mint* for O. Eng. *mynet*, *church* for O. Eng. *cyrice*, *p'lice* for *police*, *b'lievs* for *believe*, *s'pose* for *suppose*; Germ. *glauben* for **ge-lauben*, *gleise* for **ge-leise*. The omission of an initial vowel is called *aphaeresis*; of a final vowel, *apocope*.

BENJ. IDE WHEELER.

Syncope: See FAINTING.

Syncretism (Gr. *συγκρητισμός*): said by Plutarch to have originated as the designation of a custom characteristic of the inhabitants of Crete, who forgot or overlooked all their internal dissensions as soon as a controversy occurred with any foreign country. In the sixteenth century the word was used to denote those attempts which were made by Pico de Mirandola, Bessarion, and others to reconcile the philosophy of Aristotle with that of Plato. But a still more extensive use for the name was found in the seventeenth century, it being applied to the views of George Calixtus and his followers, who hoped to heal the schism of the Christian Church by acknowledging the traditions of the first Christian centuries besides the Bible, and declaring the *Symbolum Apostolicum*, the common basis of the various Christian denominations, as sufficient for the definition of true Christianity.

Synecdoche [= Lat. = Gr. *συνεκδοχή*, liter., an understanding of things together or of one thing with another; deriv. of *συνδέχεσθαι*; *σύν*, with, together + *δέχεσθαι*, understand, liter., take from; *δέ*, from + *δέχεσθαι*, receive, take] a figure of speech which displaces an ordinary term by one which naturally suggests it, on account of the relation whole to part or part to whole, genus to species or species to genus; thus *city* for *people* of the city, *blade* for *sword*, *bald-head* for *bald-headed man*, *bird* for *fighting-cock*, *man* for *humankind*, etc. See METAPHOR and METONYMY.

BENJ. IDE WHEELER.

Synergism [deriv. of *synergy*, from Gr. *συνεργία*, a working with, assistance, deriv. of *συνεργῶν*, work with, assist, deriv. of *σύνεργος*, working with or together; *σύν*, with, together + *εργον*, a work]: in theology, the view that God and man share in the work of regeneration, the human will responding to the Spirit of God. So Melancthon taught, opposing the view of Luther as to the bondage of the will and its complete passivity in conversion. Flacius and his party charged Melancthon with teaching that the human will had the initiative in conversion. This misunderstanding was repudiated by Melancthon, who endeavored to make his meaning clearer by employing other phraseology. This difference of opinion in regard to the will led to vehement and long-continued controversies, and divided the Lutherans into the Flacians, or the orthodox, and the synergists. The former carried the day in the Formula of Concord (1577), but few modern Lutherans defend their view. See REGENERATION and CONCORD, FORMULA OF.

SAMUEL MACAULEY JACKSON.

Syne'sius: bishop, philosopher, and poet; b. in Cyrene, the civil metropolis of the Libyan Pentapolis about 375; studied philosophy in Alexandria under Hypatia, of whom he became an enthusiastic disciple; was sent at the head of a provincial embassy to the Emperor Arcadius at Constantinople in 397, and stayed there for three years, which time he describes as exceedingly painful; visited Athens in 402, but found himself greatly disappointed, and spent most of his time in rural retirement near the frontier of Cyrenaica, occupied with the study of philosophy and literary pursuits. In 410 he was elected Bishop of Ptolemais, the ecclesiastical metropolis of the province, but his relation to Christianity previous to his election is rather obscure, and it can not be made out with certainty whether he was baptized or not. He accepted the election with great reluctance. Many of the Christian doctrines he could not reconcile with the ideas of the Neo-Platonic philosophy which formed his innermost conviction. The date of his death was about 415 (Zeller). Of his works are extant several essays, among which are *De Insomniis*; several orations, among which that held before Arcadius (*De regno*); a number of hymns, often translated into modern European languages, and considered to be the finest specimens of mysticism in its highest flights; and letters of great interest. Collected edition, with Latin translation, by Petavius (Paris, 1612; 2d ed. 1640); critical

editions by Krabinger of separate works. See H. N. Clausen, *De Synesio* (Copenhagen, 1831); C. Thilo, *Commentarii in Synesii Hymnos* (Halle, 1842-43); and Volkmann, *Synesius von Cyrene* (Berlin, 1869).

Revised by W. T. HARRIS.

Syngnath'idæ [Mod. Lat., named from *Syngnathus*, the pipe-fish, the typical genus: Gr. *σύν*, together + *γνάθος*, jaw]: a family of marine lophobranchiate fishes. The form is much elongated with little flesh, the body is almost covered with partially ossified plates, the head and snout are long and tubular, and the males have pouches in which the eggs of the female are hatched. They attain a length of 2 or 3 feet, live upon small marine animals and the eggs of other fishes, and have great affection for their young, which often return to the egg-pouch of the male parent for protection. Not all the pipe-fishes belong to this family, that name being often given also to the fishes forming the family *Fistulariidae*, also called pipe-mouths and flute-mouths.

Synize'sis [Gr. *συνίζησις*, deriv. of *συνίζω*, sit down together, sink together; *σύν*, together + *ίζω*, to sit]: the blending of two vowels into one syllable. The term is generally used of vowel-contractions not indicated in the written form of language. Thus when in Homer the words *τέλχεα*, *ἡμῶς* are scanned as disyllables without change of written form, the phenomenon is called synizesis, but when, as in Attic Greek, the written form presents *τέλχ'α*, *ἡμῶς*, the change is called contraction, or synæresis, the opposite of diæresis. It is only in terms therefore of the written and not of the spoken language that synizesis differs from contraction. Contraction between vowels of different words is called *crasis*.

BENJ. IDE WHEELER.

Synod [viâ Fr. from Lat. *synodus* = Gr. *σύνωδος*, a coming together, meeting, synod; *σύν*, together + *ὁδός*, way]: an ecclesiastical assembly or council. Synods may be local, diocesan, or œcumenical; for the last, see COUNCILS, ŒCUMENICAL. The supreme body of the Russian Church is the Holy Governing Synod. In the Presbyterian Church the synod is the ecclesiastical court, composed of lay and clerical representatives, which comes between the presbytery and the General Assembly. In the Northern Presbyterian Church it takes in, generally speaking, the presbyteries of only one State, and is composed of delegates chosen by these presbyteries. In the Reformed Church (Dutch and German) the highest court is called the General Synod, the next in rank the Particular Synod. The word synod is also used in the Lutheran Church, both on the Continent and in the U. S., for a church court composed of clerical and lay delegates. The synods in Reformation times in Germany were exclusively clerical; but the earliest in which the lay element, now an integral part, appeared was that held in Paris in 1550. S. M. J.

Synodites: See CENOBITES.

Synod of Dort: See DORT, SYNOD OF.

Synonyms [from Fr. *synonyme* < Lat. *synonymum* = Gr. *συνώνυμον*, synonym, liter., neut. of *συνώνυμος*, having the same name or meaning; *σύν*, together + *ὄνομα*, name]: words so nearly equivalent in meaning as to be in some of their uses interchangeable. In a thoroughly organized and digested language it is doubtful whether two words are ever perfect synonyms for all purposes. The superfluous material which tends to accumulate in a language, especially a literary language, through the formation of new derivatives, the widening and shifting of signification, and the introduction of loan-words (see DOUBLET), is either applied by differentiation to the indication of special phases or shades of meaning or is discarded in the survival of the fittest. Conscious discrimination of the exact values of synonyms is often a most difficult task. Books which aid in this are: Smith, *Synonyms Discriminated* (4th ed. London, 1890); Crabbe, *English Synonyms Explained* (revised ed. 1891); Roget, *Thesaurus of English Words and Phrases* (n. e. London, 1833, a particularly useful book); Schmidt, *Synonymik der griech. Sprache* (5 vols., 1876-86, the best work of its kind); Döderlein, *Lateinische Synonymik* (6 vols., 1838); Shumway, *Handbook of Latin Synonyms* (based on the German of Meissner, 1884; this, as well as preceding, unsatisfactory); Trench, *Synonyms of the New Testament* (11th ed. London, 1890); Eberhard, *Synonym. Handörterbuch der deutschen Sprache* (2d ed. 1888); Sanders, *Bausteine zu einem Wörterb. der sinnverw. Ausdrücke im Deutschen* (1890); Lafaye, *Dictionnaire de Synonymes Franç.* (1878, good); Tommaseo, *Dizionario dei Sinonimi della lingua Italiana* (1867).

BENJ. IDE WHEELER.

Synovial Membranes (*synovialis* is from Gr. *syn*, with + *laos*, a row, agg.; connective tissue) membranous structures which surround the closed cavities connected with the joints, or occur about certain tendons or between opposed movable surfaces; they resemble serous membranes in structure, but are distinguished from them by the viscid or glairy character of the synovial fluid or synovia with which they are intercalated, in contrast to the thin watery secretion bathing the serous surfaces. The synovial membranes consist entirely of connective tissue, between the closely folded lamellae of which numerous branched or spindle cells are situated; the free inner surfaces of these membranes are invested with an unperfected layer of flattened cells, which, in places, closely suggest an endothelium, while, in other localities, thin plate-like elements are replaced by loosely grouped branching cells. There are three classes of synovial membranes in the human body: (1) The articular line the walls of the closed cavities of the joints, and secrete a fluid to lubricate the opposed cartilaginous surfaces of the articulating bones, over whose surfaces of contact, however, no part of the articular membrane extends, as it falls away and terminates a short distance before reaching the articular facets. (2) Vaginal or sheath-like synovial membranes surround the tendons when passing through osseofibrous canals or grooves in the surface of bones, as is the case in the hand and foot. (3) Bursal (Gr. *bursa*, a bag) little synovial sacs or cushions, are interposed between parts moving one upon the other with friction, as where a tendon glides over or presses directly upon a bony prominence. The synovial fluid consists of nearly 95 per cent. of water, rendered viscid by mucus, unabsorbable cells, fat, albumen, and salts. The synovial membranes are frequently the seat of disease. Acute synovitis, acute inflammation, may attack any joint as the result of violent injury, exposure to cold, rheumatic taint, or less often from vitiated blood in the course of fevers and other diseases. The symptoms are local swelling, extreme tenderness upon touch or pressure, pain when moved, and often persistent agonizing pain caused by the distension of the sensitive inflamed cavity by a hypersecretion of fluid. Penetrating wounds of the large synovial cavities, whether punctured, lacerated, or occurring in connection with fractures, are serious, often necessitating the loss of a limb. Chronic synovitis is often a product of tubercular or scrofulous hereditary taint with injury or over-use as the exciting cause. The destructive process often involves the ends of the bones and the ligaments, which are softened and disintegrated. Abscess, partial dislocations, and ankylosis, or stiff joint, are the chief misfortunes which result. The synovial bursa often become swollen and prominent by hypersecretion, and also by injury and inflammation; such is the "weeping elbow" of the back of the wrist, which resembles a cystic tumor. Its contents must be evacuated and the membranes are irritated or lacerated to disperse it by adhesive inflammation. The occurrence of dislocated hurses, and difficulty of cure in recent cases, are due to their connection with the cavity of an adjacent joint.

Revised by G. A. PRINCE.

Syntax (Gr. *σύνταξις*, arrangement, organization, the organization of elements, as the elements of speech, into a larger whole; commonly used by the Greek grammarians in the stricter sense of the arrangement of words to form the sentence; *σύν*, together + *τάξις*, to arrange); the science which treats of the sentence and its organization and of its constituent parts. In the following article it is not the purpose to consider the syntax of languages in general, but only that of the Indo-European languages, and that, too, only in so far as it admits of a comparative treatment. In the vast field of the literatures of the Indo-European peoples there appears only at two points the independent beginning of a grammatical science, as well as of a syntax, namely, in India on the one hand, and in Greece on the other. The Hindus failed to recognize syntax as a distinct department of grammar, but scattered their syntactical observations at various points in the body of their grammatical doctrine. It is possible even for one not versed in Sanskrit to gain some impression of this body of doctrine through Otto Böhtlingk's second edition of Pāṇini, in which the rules laid down by this prince of Indian grammarians are given in accurate German translation. (1) Böhtlingk, *Pāṇini's Grammar*, Leipzig, 1897; cf. also Th. Bouley, *Geschichte der Sprachwissenschaft*, Munich, 1897, pp. 85 ff.) In order to gain a correct appreciation it must be remembered that from very early times Sanskrit, i. e. the language of the upper

classes, which stood in contrast with the language of the people, was a subject of instruction. That is to say, a litetus was shown by means of grammatical instruction what forms were to be used in polite speech, when he had a particular thing to say. Thus, for instance, he was taught that when he wished to report something that had occurred that day he was to use the aorist; when he wished to indicate the agent, which accompanies a verb, the nominative or the instrumental. That the Indian syntax takes its starting-point with that which one wishes to say, the necessity for the expression of ideas, whereas we in our modern discussions choose the external form as the starting-point. Though our procedure is unmistakably the more correct, we may nevertheless learn much from the Hindus, for they were scrupulous observers, paid attention, and insisted upon precise and clearly intelligible expression. The Hindus would never, for instance, be guilty of so absurd a rule as that familiar in the German schools: "Auf die Frage 'wan?' nicht der Dativ," "the dative answer to the question to whom? or for whom?"—which in reality expresses nothing more than that a dative in the question is often matched by a dative in the answer. As the best contributions which the Hindus have furnished in this field may be regarded their doctrine concerning composition, a subject which we commonly discuss at the end of the inflexions, but which may fairly claim a place also in the syntax, and their theory of the cases which is set forth in Delbrück's *Comparative Syntax* (I, 172 ff.). The Indian method of regarding language was denied a permanent influence upon modern grammar, if for no other reason, because of the late period at which it became known, or at least became generally accessible. Concerning the grammatical system of the Greeks we have, besides numerous monographs, a comprehensive work by H. Steinthal, *Geschichte der Sprachwissenschaft bei den Griechen und Römern* (2d ed. Berlin, 1900). The first part embraces the theories of the Greek philosophers, in which was found the source equally of instruction and confusion for syntactical theory. The second source of the Greek grammatical system was the study of the Greek classics which reached its formal acme in the Alexandrian period. From the Greek grammatical system, resting upon these foundations, is derived the entire grammatical structure used by the modern world, as well as also the greater part of the syntactical concepts. (Cf. introduction to *Comparative Syntax*, vol. I.) The term *σύνταξις*, *syntaxis*, was used very early, namely, in the *Zoëne* of Theophrastus Thrax, written probably in the first century B. C., where the definition of a part of speech reads as follows: *λέξις ἑστὶ μέρος ἰδιότροπον καὶ ἀνὰ σύνταξιν λέγειν*, i. e. a *λέξις* is the smallest division, or the unit of the organized sentence. Syntax first appears as a special part of grammar in the well-known work of Apollonius Dyscolus (probably middle of second century A. D.). For a correct understanding of the work *ἡτοιμασμένη*, it is necessary to remember that there already existed distinctions of the parts of speech, and that in single cases certain expressions had already been noted as grammatically correct or incorrect. Apollonius sought, however, to determine wherein the grammatical correctness or incorrectness lay. It depends with him upon whether the *κατάστημα*, the correspondence of the forms, has been recognized or not; for instance, whether with a singular noun the singular or perhaps the plural of a verb has been used, whether or not the case representing the correct idea has been used with the verb or not. He treats therefore of what is later brought together under the head of agreement and of government. This constitutes, however, only the central topic of his work; connected therewith are careful discussions concerning the character of various parts of speech, e. g. of the article. The later syntax adopted from him not only various definitions of fundamental grammatical concepts, but also the outlines of the doctrine concerning *anastrophe* and *ellipsis*. Through the Roman grammarians, particularly Priscian, his syntax (*immutatio*) was handed down to the Middle Ages. Here it fell naturally into the hands of philosophy, where, until the beginning of the sixteenth century, it remained. In the introduction to the *Comparative Syntax* cited above it has been shown how one after another the scholastics, then Locke, Kant, Hegel, Herbart, exercised a determining influence upon the development of grammatical conceptions, but with the opening of the nineteenth century these currents of influence, all independent of philosophy, combined to reshape the methods of syntactical research, namely: (a) The more accurate study of the Greek

and Latin texts, by which a purely empirical treatment of syntax became possible, as it, e. g., appears in the Greek grammar of Matthiae (A. Matthiae, *Ausführliche griechische Grammatik*, Leipzig, 1807); (b) the awakening impulse of Teutonic philology, connecting itself with the name of Jakob Grimm, who first taught how grammar, including syntax, can be treated historically; and (c) the science of comparative philology, which established for the study of syntax as well as of all linguistic phenomena a foundation reaching down into most primitive times.

The representatives of the comparative science of language occupied themselves first with the cases. Here it was at once observed that Sanskrit contains, besides the cases occurring in Latin, also the locative and the instrumental. This led directly to the conclusion that these cases, and perhaps still others, must have existed in primitive times. What now has become of these extra cases in the different languages, e. g. in Greek? The idea readily suggests itself that they had been absorbed into the other cases; for instance, the ablative into the genitive, the instrumental and locative into the dative. It is difficult to say who first gave expression to this conception, which is summarized under the term *syncretism*; it was certainly first developed in detail by Delbrück (B. Delbrück, *Ablativ, Localis, Instrumentalis*, Berlin, 1867). Here follows, besides a variety of monographs, the important work of Hübschmann (*Zur Casuslehre*, Munich, 1875), which contains not only a good history of the theory of the cases, but also adds a treatment of Iranian case-usage, to which Delbrück had given little or no attention. Then follows Gaidicke, *Der Accusativ im Veda*, (Breslau, 1880), a superb piece of work, full of ideas and covering a larger field than the title promises, a book which every syntactician is recommended to study. A first attempt in the study of the structure of the sentence was made by Ernst Windisch in an article on the origin of the relative pronoun (*Curtius' Studien*, ii., Leipzig, 1869). Even though the main idea, namely, that the relative was developed only in the separate languages, may perhaps be incorrect, yet the presentation of the pronominal usage in the different languages was important and suggestive. The syntax of the verb is the general subject of a series of works which appeared in the *Syntaktische Forschungen* (Halle, 1871-), published first by Delbrück and Windisch conjointly, later by Delbrück alone. In these the attempt is made to trace through the usage of the two languages compared the uniform fundamental idea of *will* for the subjunctive and of *wish* for the optative, in doing which it was necessary of course to construct a theory for the development of the different forms of the sentence. In this work the presentation of the actual existing facts of Vedic syntax was notably insufficient. This it has been the purpose of the *Altindische Syntax*, to be mentioned later, as far as possible to correct. In immediate connection with these first attempts there appeared in 1872 a work of Ludwig Lange, *Ueber den homerischen Gebrauch der Partikel el* (*Abhandlungen der sächsischen Gesell. d. Wiss.*, 1872, vol. vi.), in which Delbrück's theories concerning the sentence-types were corrected and complemented, and an example given of statistical treatment of an individual phenomenon which has seldom been paralleled. A foundation for the study of tense is presented in the second volume of the *Syntaktische Forschungen*, *Die altindische Tempuslehre*, by B. Delbrück (Halle, 1876), in which was especially demonstrated that the Sanskrit has an aorist usage which, as may be shown, though not shown in this work, corresponds in substance with the Greek and the Slavic usage. In reference to the verb is to be added the work of Julius Jolly, *Geschichte des Infinitivs im Indogermanischen* (Munich, 1873). The infinitive is nothing more than a case introduced into the verb system.

Of prime importance for comparative syntax is the *Vergleichende Syntax der slavischen Sprachen*, by Franz Miklosich (Vienna, 1868-73). Though the theoretical outlines of this work are in many regards unsatisfactory, and the comparison of the different Slavic languages with each other and of the Slavic with other languages is not sufficiently true to historical method, yet all the defects of this excellent work are redeemed by the presentation of an inexhaustibly fresh body of language-material, from which all subsequent writers have drawn and continue to draw. In Miklosich's syntax the idea of the sentence scarcely claimed a proper place. Thus there is lacking, for instance, a chapter on the order of words. How much is to be observed, however, in this field has been illustrated in an article of A. Bergaigne, *Mém. de la soc. de linguistique* (vol. iii., Paris,

1875), and in the third volume of the *Syntaktische Forschungen*, *Die altindische Wortfolge aus dem Çatapathabrâhmana* (Halle, 1878), which limits itself, however, to the Sanskrit. The fifth volume of the *Syntaktische Forschungen*, *Altindische Syntax*, by B. Delbrück (Halle, 1888), deals also with the Sanskrit, while the fourth volume contains sketches in Greek syntax.

All these works, and such others as might be added, contain only special discussions, and seldom venture upon the field of theoretical inquiry. A summarizing treatment is attempted in Delbrück's *Vergleichende Syntax* (part i., Strassburg, 1893; Engl. transl. *Comparative Syntax*), which forms the continuation of Brugmann's *Grundriss der vergleichenden Grammatik der indogermanischen Sprachen*. Theoretical discussions appear in an earlier work of Ludwig Lange, *Ziel und Methode der syntaktischen Forschung*, an address at the *Göttinger Philologenversammlung*, 1852; also in the *Prinzipien der Sprachgeschichte*, by Hermann Paul (2d ed. Halle, 1886); and finally in the above-mentioned introduction to Delbrück's *Comparative Syntax*. What follows will be devoted to a brief statement of certain theoretical considerations.

I. *Limits and Classifications of Syntax*.—As regards the question how syntax is to be defined and limited in reference to other departments of grammar, complete agreement has not yet been reached, as indeed it has not been reached regarding the mutual provinces of the grammar and the lexicon; it is, for instance, still customary to discuss in the grammar certain things like the numerals, which properly belong only in the dictionary. This need not, however, be regarded as strange. In questions of this sort are involved not only difficult matters of principle, in reference to which the stubbornness of scholars is wont to assume monumental proportions, but also practical considerations and necessities. Every author desires to present a comprehensive treatment of his material, and every one who wishes to avoid discourtesy feels himself hampered by the traditional views and usages of his readers. Apparently all are now of the opinion that one thing belongs with certainty to syntax, namely, the doctrine concerning the organization of the word-forms into the sentence, i. e. the doctrine of the sentence in the narrower sense. An exception appears, however, it must be admitted, in F. Miklosich, who expresses himself as follows concerning the conception of syntax: "That department of grammar which undertakes to set forth the signification of the word-classes and word-forms is called syntax; syntax is accordingly divided into two parts, of which the one deals with the signification of the word-classes, the other with the signification of the word-forms." Under this limitation of the conception, however, the author himself is often involved in embarrassment. Thus the verbs without a subject, which we commonly call the impersonal verbs, he has been obliged, inasmuch as he does not recognize a doctrine of the sentence, to include in an appendix to the nominative. The order of words he has not discussed at all, though there is undoubtedly a traditional type of word-order in the Indo-European languages as well as in the Slavic. Miklosich was evidently led to this view by an exaggerated empiricism. He insisted on recognizing only the facts of tradition, and the union of word-forms into the sentence did not seem to him traditional, but a product in each several case of the free choice of the speaker. This view is, however, incorrect. As already indicated, certain types of word-connection and word-order are transmitted as psychological realities, and even one who declines to recognize psychological realities must yet allow that there is an objectively perceptible part of a sentence, namely, the sentence accent, which is in and by itself a matter of actual tradition. That we do not indicate this in writing is a matter of accident. It is in no way less real than the accent of individual words. Certainly one can not doubt that the interrogative sentence differs in the traditional accent from the declarative sentence, or that the differences between dialects express themselves with especial distinctness in the different accentuations of the sentence.

Besides the doctrine of the sentence in the narrower sense, we commonly include under syntax the doctrine of the parts of speech. Many scholars, to be sure, decline to admit this, and prefer to classify grammar under the heads doctrine of sounds, doctrine of forms, doctrine of signification, doctrine of sentence-structure. This is at bottom largely a matter of terminology. It is of slight importance whether a given part of the grammar is classed as the first part of syntax or by itself as the doctrine of signification. It is a

fact of more importance than there is disagreement concerning what may be included under the chapter on the parts of speech. Under the noun, *e. g.*, involved the different kinds of substantives—concrete, abstract, simple, compounded, *etc.*—gender, number, case. The different kinds of nouns were discussed by Brugmann under the head of stem-formation, but not the subject of gender, and so it happens that in Dehnbach's *Comparative Syntax*, which supplements Brugmann's *Grundriss*, there is no chapter on the different kinds of nouns. Similarly with other points. In general, however, it is agreed that the treatment of the parts of speech falls under the syntax, or constitutes an introduction thereto. How is it with other points, which less frequently claim discussion? Where, for instance, shall the sentence-mood be treated? It is related to the sentence as the word-concept to the word. This would seem to assign it to the phonology (doctrine of sound), or to the inflexion (doctrine of form). It is impossible, however, to separate it from the doctrine of word-order, with which it is most intimately connected, except as one is ready to sacrifice comprehensiveness and intelligibility to the demands of a rigid schematism. The writer consequently has deemed it best to treat of the sentence-mood under the syntax, thus, *e. g.*, in his *Atlantische Syntax*, pp. 26 ff. As it is with the definition of the boundaries of syntax, so with the question of arrangement and classification. It is unavoidable that here also theoretical and practical considerations should often cross each other's track. It must above all things, however, be remembered that the demands of a reasonable systematization, by no means require that a given subject should receive mention but once. It is essential, for example, to treat all the cases together, so that forms of usage which have mutually influenced each other may not be torn asunder. It is, however, on the other hand, necessary to mention certain cases where the relation of subject and predicate is under discussion, *i. e.* in the doctrine of the sentence proper. Under these circumstances it must be no cause of surprise when the same author adopts now one and now the other arrangement.

3. *The Office of Syntax.*—The conception which one forms of the office of syntax will depend upon his views of the aims of linguistic science as a whole. There have been leading scholars, for instance, August Schleicher, who classed the science of language with the natural sciences, and who regarded it therefore as their office to identify laws within language after the analogy of physics or chemistry. Whether such a possibility may exist in the field of phonology can not be investigated here, certainly for syntax such a thing is out of the question. For this reason, indeed, Schleicher proposed to separate syntax, as far as consideration of function is concerned, from the other parts of grammar. Most philologists regard the science of language, however, as an historical discipline. In connection herewith, the older scholars, *e. g.* Franz Bopp, attempted to push their investigations to the beginnings of everything. They had confidence in their ability to discover the origin of the Indo-European languages, or at least of the grammatical forms. Inasmuch now as the understanding of the origin of the grammatical form would yield at the same time a knowledge of the primitive meaning, these investigations concerning the origin of inflexion would furnish at the same time a point of departure for historical syntax. The hopes and claims of present-day scholars have, however, assumed much more modest proportions. We are now, it may be believed, universally convinced that but little can be learned of the origin of inflexion, and that even this scanty knowledge is too uncertain to serve as a foundation for a structure of syntax. We now recognize the object and office of the science of language to lie in tracing out historically a specific study of linguistic development, whether through direct observation, or, as is the case in the comparative science of language, through combination. In this is involved, then, the assertion that syntax is an historical science. Its office may be in detail somewhat more accurately defined, when we have considered the question what is actually handed down within a language from one generation to another. Self-observation shows directly that this is not limited to a series of words and forms, but includes also a vast number of word-combinations of various sorts, certain connections between verb and noun, proposition and case, agreement between substantive and adjective, word-order, *etc.* In short, a great number of types, whose real existence may be proven by the fact that the speech-sense immediately results when an expression is attempted which offends against a tradi-

tional type, *e. g.* if one should attempt to put the adjective after the noun. The classification of these types is the proper office of syntax. Within the limits of an Indo-European language it is to be observed how these types exist, *whether, and away, etc.* It is, usually, to be observed which types are handed down from primitive times, and which are relatively recent products. In an examination of this sort it would, for instance, be found for Greek that the most of the cases of the finite verb are handed down from primitive times, but not so the uses of the infinitive, also not the use of the accusative with the infinitive, and so with the whole system of construction in the indirect discourse, which last is therefore a special product of the Greek. It is different with the noun, where the construction-types of the different cases have blended together; and in the course of time the dual has been lost.

In those very simple considerations is involved a conclusion which is in point of method of high importance. What it has been shown, for instance, that the accent of the Greek was not developed within that language, but is a primitive structure with a primitive type of usage, it then becomes impossible through observation of the Greek alone to establish the fundamental value of the accent; so, therefore, the whole body of fundamental values assigned on the basis of a single language becomes untrustworthy.

In accordance with what has been said, the task of a syntactician in the field of Indo-European grammar may be briefly summarized as follows: He is to collect with all possible completeness the instances of the type of usage to be discussed, seek to trace its historical development within the individual language, compare the use of the corresponding form in the cognate languages, and seek to determine in this way the Indo-European value of the form in question. This chief value is the fundamental conception. This may be simple or complex. As to how a form came to this use one can never, or almost never, say anything with certainty. For syntactical terms, see especially *Verbum*, also *Nomen*, *Præteritum*, *Gerundium*, *Participium*, *Præteritum*, and *Indo-European Language*. R. DELAFLEUR.

Translated by Rev. J. W. WHELAN.

Synthesis: See CHEMISTRY.

Synthesis, or Assimilation [*synthesis* is from Gr. *σύνθεσις*, a putting together, combination; *syn*, together + *thesis*, place]: the fact of acting or unity in all mental operations. The principle of assimilation, made much of in recent discussions, clearly illustrates not only that an image may be as strong and habitual in consciousness as to assimilate new experiences to its form and color, but also that this assimilation or synthesis is the very mode and method of the mind's digestion of what it feeds upon. Consciousness constantly tends to neglect the unit, the *self* it proposes, the incongruous, and to show itself receptive to that which in any way conforms to its present stock. A child after learning to draw a full face—circle with spots for the two eyes, nose, and mouth, and projections on the sides for ears—will persist, when copying a face in profile, in drawing its circle, with two eyes and two ears, and fail to see its error, although only one ear is visible and no eyes. The external pattern is assimilated to the memory copy, or in the word or other symbol which comes to stand for it. The child has a motor reaction for imitating the latter: why should not that answer for the other as well? As everybody admits, in one way or another, such assimilation is at the bottom of recognition, and of illusions which are but mistaken recognitions.

It is commonly held that assimilation stands midway between absolute identity of presentations, on the one hand, and such difference of presentations, on the other hand, as is found in the relative independence of associated ideas (see *Association* or *Idiosyncrasy*), such as, for example, the association "stable—horse." But this is not the true view of assimilation, for there is no such thing as absolute identity of presentation, or of mental content of any kind. Assimilation is always present. It is the necessary basis of the earliest association. For association is, on the organic side, and at the start, only another statement for the consolidating of the different reactions which arise when the stimulations are multiple or not simple. These reactions are reduced to orderly habitual discharges—this is association by assimilation, more or less adequate to give the sense of synthesis, or unity, or identity. Association has, accordingly, a motor foundation from the first. The elements held together in memory because they are used together in action. And as

the action becomes one, but yet complex, so the mental content tends to become one, but yet complex also.

This becomes more evident when we call to mind that the "objects" of the external world are very complex mental constructions. They are, for the most part, made by association. Objects have some very general aspects in common, such as color, resistance, odor, etc. But these bare qualities, taken alone, might go to constitute one object about as well as another; and really would constitute none. What kind of an object such or such a bare stimulus shall turn out to be—this is largely a matter of association and suggestion. Hence if the mind has to construct anyhow, in each case, and to depend largely upon memory of earlier instances for its material, then it falls back at once upon those habitual reactions by which groups of associated elements are reinstated together and as one content. These old groups thus usurp the new elements by assimilation, if it be within the range of organic possibility.

Generally, therefore, it may be said that assimilation is due to the tendency of a new sensory process to be drawn off into performed motor reactions; these preformed reactions in their turn tending to reinstate, by the principle of imitation, the old stimulations or memories which led to their preformation, with all the associations of these memories. These memories, therefore, tend to take the place or stand for the new stimulations which are being thus assimilated.

All perception is accordingly a case of assimilation. The motor contribution to each presented object is just beginning to be recognized in cases of disease called by the general term *apraxia*, i. e. loss of the sense of the use, function, utility, of objects. A knife is no longer recognized by these patients as a knife, because the patient does not know how to use it, or what its purpose is. The complex system of elements is still there to the eye, all together; the knife is a thing that looks, feels, etc., so and so. This is accomplished by the simple contiguous association of these elements, which has become hardened into nervous habit. But the central link by which the object is made complete, by which these different elements were originally reproduced together by being imitated together in a single act—this has fallen away. So the APPERCEPTION (*q. v.*), the synthesis which made the whole complex content a thing for recognition and for use, is gone in these cases. J. MARK BALDWIN.

Syphax: See MASINISSA.

Syph'illis [Mod. Lat., from *Syphilus*, name of a shepherd in the Latin poem of the Italian physician Fracastorius (1483-1553), *Syphilus*, *sive Morbus Gallicus*; (irregularly) Gr. *σῦς*, hog, swine + *φίλος*, loving]: a specific, chronic, contagious disease, peculiar to the human organism, and always more or less closely associated with the venereal act. It is always acquired through contact with a human, being already suffering with the disease, or from some material which has been in contact with the discharges from a syphilitic individual. In the poem by Fracastorius *Syphilus* is afflicted with the disease by Apollo in punishment for paying divine homage to his king instead of to the god. Under various names the disease has been described in the earliest written history of every part of the globe. One Chinese account of it dates back to the writings of Hoan-Ti, B. C. 2637. In India its record appears in the *Ajura Vedas* of Suerutas, A. D. 400. Hippocrates and later writers describe it as existing among the ancient Greeks. Celsus speaks of it among the Romans. The Abbé Brasseur de Bourbourg writes that numerous documents in the languages of the tribes of the valley of Anahuac have proved to him conclusively the existence of syphilis in America prior to the discovery of Columbus. Those who read the Old Testament attentively, particularly certain psalms of David, may find ample evidence of the existence of the disease among the nations and tribes of the Orient in biblical times. The existence of syphilis in very remote periods of the history of mankind is thus demonstrated; but the first well-authenticated record of its recognition in Europe dates from the year 1494, when a notorious outbreak occurred in the army of Charles VIII. of France, who was then besieging Naples. It was characterized by ulcers upon the genitals, pains in the bones, and eruptions upon the skin, and was known then as the *morbus Gallicus* or French disease. It spread to a fearful extent, and became a veritable terror in the land. Its cause was attributed to almost every imaginable influence except the right one. Later it was recognized as the result of venereal contact, and was then claimed to have been introduced into Europe by the followers of Columbus.

In the literature of those times, the disease was usually known in each country by the name of some other country, and was designated as the *mal Anglais*, *morbus Gallicus*, *maladie de Naples*, *pox*, *lues venerea*, etc. Later it was regarded as distinct from the contagious genital ulcers whose effects were simply local, and also from gonorrhoea, although so late as the time of John Hunter this distinction was not known to him, having been for a time lost sight of. The present accurate classification of venereal disease is in large measure due to Ricord, of Paris, who published extensively concerning the subject in 1831. Later, in 1852, his pupil, Bassereau, made clear the difference between the local ulcer i. e. "chancroid," the local lesion followed quickly by constitutional infection (see *VENEREAL ULCER*), syphilis, and the other local infection of mucous membranes known as gonorrhoea. Since this time and almost up to the present day a few writers have claimed, however, the unity of the poison producing the first two lesions. Others have stoutly maintained their duality or distinctness, and this view is now positively accepted by all writers of distinction.

Effects of the Disease.—The nature of syphilis and the manner in which the human system is infected by it are yet undetermined. Opinions concerning these subjects have been very numerous and variable. A number of investigators have at various times detected micro-organisms, some of these being bacteria, which they have thought to be the active agents in producing the disease, but research has shown that the presence of these micro-organisms does not account for the disease. The problem must be solved by different methods of investigation, yet higher powers of the microscope, or the introduction of some entirely new methods of studying the discharges.

When this poison of syphilis is inoculated upon a healthy surface, it shows no immediate signs of virulence, and healing of the wound takes place promptly, as if no such inoculation had occurred. Then ensues a period of complete rest, the so-called period of incubation, varying from ten to seventy days, when a thickening or induration of the integument or mucous membrane at the point of inoculation is noticeable. Soon a discharging lesion results, the discharge being extremely infectious. Inasmuch as this lesion is surrounded by a zone of tissue induration, i. e. cell proliferation, we have an ulcer or a papule, situated upon an indurated basis; and this is known as the chancre, or initial lesion of syphilis. Then occurs another period of apparent rest, the so-called secondary incubation, during which there is little or no consciousness on the part of the patient of the trouble brewing in his system, the local disease manifestation frequently healing with or even without the proper treatment. This secondary period continues for from four to six weeks, perhaps longer, when the lymphatic nodes in all parts of the body will be found enlarged and hardened, and there breaks out upon the surface of the body a rash or eruption, usually more or less resembling that of measles. This is seen most commonly upon the thorax and abdomen, from whence it may spread to all parts. This rash, usually known as syphilitic roseola, marks the second or constitutional stage of syphilis. Then, or within a short time, the patient begins to experience constitutional disturbances chiefly at night, including pains in the bones, increase of temperature and general discomfort, which is usually known as syphilitic fever. This stage is still further characterized by the tendency to engorgement and inflammation of those parts containing much lymphatic tissue, such as the tonsils, the pharynx, the soft palate, etc. If unchecked the eruption assumes more of a papular type, the papules varying in size from that of a pinhead to that of a split pea, occupying the upper part of the body usually, commonly symmetrically distributed, but not often ulcerating at this time. This is the papular or secondary eruption of syphilis, sometimes assuming rather the pustular type, or becoming pustular as the result of a depraved state of the system. The papules which occur upon the mucous membrane discharge a most infectious material, and are known as mucous patches. They may be found upon the membranes of the mouth, the inner surface of the nose, the eyelids, and about the genitals; while papules upon the skin wherever there is abundant secretion and moisture often assume the characteristics of mucous patches, and are spoken of as mucous tubercles. The secretions from both of these lesions being so highly inoculable constitute one of the most important dangers in dealing with the disease. Inoculation of a healthy person with syphilis frequently occurs through contact with the secretions of a mucous patch situated in the mouth, as in

knowing, the only required condition being a scratch, erosion, or simple abrasion, like a cold-sore, on the part of the one who has not suffered previously from the disease. Numerous examples are recorded where the disease has been acquired from contact with a spoon, pencil, pipe, stick of candy, plug of tobacco, etc., which has been contaminated from such secretions. Chancres occur also in other parts of the body as the result of innocent contact on the part of persons who are totally ignorant, or at any rate unsuspecting. Syphilis thus acquired is known as syphilitic inoculation, or "syphilis of the innocents." Fortunately, the syphilitic principle requires for its introduction and successful inoculation, in almost every instance, a pre-existing lesion of the skin or mucous membrane. But it has been transmitted through the instruments of the surgeon or dentist, by hypodermic syringe needles, and in other ways which are often difficult to trace. A specific inflammation of certain tissues of the eye, particularly of the iris, is a common occurrence in early constitutional syphilis, which is followed by more or less pain, often severe, by photophobia or fear of light, by irregularity of pupil, due to exudation and adhesion, etc. Later in the course of the disease the various structures of the eye may suffer seriously, and syphilitic affections of all the central tissues are known and carefully described.

Changes in the bones are often associated with the active or secondary period of syphilis. Sometimes these are of wandering character; again, they are localized. The periosteum, or covering membrane of the bone, is often thickened, as the result of which bony elevations, termed nodes, result. The nails and the hair also are frequently affected, the hair losing its luster and falling out, often in spots; at other times complete baldness results. The nails may become dry, lusterless, and brittle, with arrest of growth. The lymph nodes and lymphatic structures throughout the body suffer seriously during the active manifestations of the disease, and the former will be found enlarged in all of these cases. The lymph nodes in the neck are most easily investigated; and a chain of nodules of this kind may be felt on either side of the neck in distinct cases of syphilis. A small lymph node just above the inner canthus, known as the supra-orbital, is almost invariably involved in this disease, and seldom in any other affection, except in septic infection of the arm. The more active manifestations of syphilis covering the first and second stages extend over a period of rarely less than one, nor more than two, years, during which time all the secretions from all ulcerative lesions are inoculable, as well as even the blood. Its course is marked by the gradual invasion of the organism, and always in the line of the lymphatic distribution. Cases vary much, however, in degree, since in one the disease may be so slight that even the lymphatic enlargements are not easily recognized, and in another as severe that even death may be the result. The causes of these differences appear to depend upon degree of virulence in the material inoculated, and upon the condition and antecedents of the patient. Syphilis may be transmitted to offspring through the influence of a syphilitic parent during the active period of the disease. From this still-births and arrests of development may result, and uterine and vesicular changes may depend upon antecedent syphilis for a long time subsequent to the termination of active syphilis. As a rule, however, syphilis is transmitted by hereditary taint only while lymphatic enlargements and involvements remain. A complete disappearance of the latter, with or without treatment, is the sign of immunity from danger of hereditary transmission.

Commonly the most serious manifestations of syphilis terminate with the arbitrary second stage, either as the result of treatment or by a natural evolution. All writers, however, recognize the existence of a so-called third, or "tertiary," stage, although no exact length of time can be named between it and the second. The tertiary is, in some instances, a gradual merging of the second stage; while in other instances it is separated from it by an interval of more or less perfect health, varying from a few months to a number of years. The products of tertiary lesions are seldom infectious. The lesions themselves are less symmetrically arranged also than are those of the second stage. They are characterized by induration or deposit of lymphatic elements in the various tissues of the body, which produce tumor formations, commonly known as gummata, or syphilitic. These tumors or new formations are of course composed of cellular aggregations, which, however, are quite prone to break down and slough. Hence many of the tertiary lesions are of the ulcerative type. In the skin there

are a variety of deposits, tending always to ulceration, by which eruptions of characteristic appearance are produced. The larger lesions of this character are usually discolored; the smaller are multiple, and are often widely disseminated. Very extensive ulceration sometimes results from lesions of this character. These are all more likely to occur in alcoholics, in the debilitated, and in the dissipated. The gummatous tumors, or gummata, may form in or beneath the skin, or in any other part of the body; and they cause the organs affected to enlarge, presenting nearly all the appearance of ordinary tumors, assuming even malignant characteristics. They are, perhaps, most common in the skin, the liver, the bones, and the brain. In any one of these places they may break down with resulting abscesses or ulcerations.

Treatment.—The treatment of syphilis has been from the earliest times a subject of controversy, and is to-day a subject on which very great ignorance prevails, especially among the laity. There can be said, however, of this disease, that there is no other serious affection which involves the human body which can be so positively influenced for good as this; in other words, there is no other disease which in just response it is so satisfactory to treat. It is necessary, however, to combat a great many popular superstitions regarding the disease, and to insist that the only correct and reliable remedies are mercury and iodine, which can be combined with various others often with good effect, whose action always needs watching, but without which little or nothing can be done. Certain mild forms of the disease, to be sure, will tend toward spontaneous recovery, and these may be aided by absolutely vegetable remedies, or by absence of treatment; but the more serious forms of the disease can not be successfully treated without the two remedies named above, and the public should be warned against men who advertise or profess to cure this disease without these measures; they are either ignorant or dishonest who make these claims. As the result of such medication in years gone by, a legitimate dread of mercury was engendered, but now, under proper watching, no evil effects need be dreaded, and the manifestations of the remedy can be controlled with as much certainty as those of the disease, when using one against the other. It is possible that both of these elements—mercury and iodine—act by causing metamorphosis of tissue and influencing cell growth, perhaps also by introducing into the system some antitoxic or antiseptic influence. There should be emphasized also the fact that syphilis is, so far as most cases are concerned, a curable disease, which offers an element of hope hitherto usually lacking. Too much pains can not, however, be taken to impress upon patients the fact that, in order to effect a cure, it is necessary to keep them continuously under the influence of these remedies for a period of time averaging about thirty months in duration. Less may answer in some cases; more may be required in others. This period of time, moreover, must begin with the last visible manifestation of the disease. Thus if a patient has been under ineffectual treatment already for three years, it will be necessary to begin then and to keep him for at least two years longer under treatment, watching its effects in such a way that neither the disease nor the remedies shall get the upper hand, but that the one shall be administered in just sufficient doses to counteract the effect of the other. Many patients treated in accordance with these principles have remained absolutely well, have married, and have propagated families in which there is not the slightest trace of any inherited affection. It is well, therefore, to maintain as publicly as possible that syphilis is, in proper hands, a curable disease, providing only that the right directions be insisted on and scrupulously followed. Syphilization, the proposed treatment of the disease by repeated inoculation of the purulent secretion of venereal sores, originated by Avelas de Tourn in 1844, met with some favor in Italy and Sweden, but elsewhere was discredited, and since 1875 has fallen into disuse. HOWELL PARK.

Syphon: See Siphon.

Syra, or Syrus (Gr. Σύρος): an island; one of the Cyclades, belonging to Greece. Area, 44 sq. miles (see map of Greece, ref. 17-L). Seldom mentioned in ancient times, it became important during the Greek revolution, when it served as a place of refuge for fugitives from the mainland and islands. Its favorable situation, good though diminutive harbor, and the enterprising spirit of its people have since rendered it the commercial center of the Aegean Sea. The island is rocky, mountainous, and generally sterile, but produces some grain, fruit, and wine, though insufficient to

support its inhabitants. Hermonopolis, the capital, built of glaring white houses, presents a striking appearance as it rises amphitheatrically and almost precipitously from the water. It has dockyards, machine-shops, hospitals, good schools, and a college. Pop. (1890) 22,104.

E. A. GROSVENOR.

Syracuse [from Lat. *Syracusæ* = Gr. *Συράκουσαι*; Ital. *Siracusa*]: chief town of the province of Syracuse, Sicily; on the east coast of the island, in lat. 37° 0' N., lon. 15° 20' E. (see map of Italy, ref. 10-G). The modern town occupies the rocky islet Ortygia (1 mile in length, $\frac{1}{4}$ mile in breadth), which serves as an irresistible breakwater to protect the large harbor on the W., across the mouth of which it lies. This harbor was formerly one of the finest in the world, and is even now the best, perhaps, in Sicily. Ortygia, though at some periods united to the main island by a viaduct or causeway, is now connected with it only by bridges. According to Thucydides, Ortygia was colonized by the Corinthians 734 B. C., though the Phoenicians had probably made an earlier settlement here. (See Gelo, Hiero, Dionysius the Elder, and Dionysius the Younger.) When, however, after long and cruel wars, the Romans obtained possession of the rest of Sicily, Syracuse, together with some important places in its neighborhood, was left to Hieron II. (275 B. C.), who had become an ally of Rome. Under this king the city rose to its highest point of magnificence, and is said to have contained an immense population within its walls, then, according to some authorities, 22 miles in circumference; according to others, 14 miles. The grandeur of the edifices and the artistic wealth and refinement of Syracuse were altogether worthy its colossal size; but in the course of the Second Punic war, Hieronymus, the successor of Hieron, broke off the alliance with Rome and joined the Carthaginians—a step which proved the ruin of his kingdom. After a long and desperate resistance, in which the celebrated Archimedes exerted all the powers of his wonderful mechanical genius in the defense of his country, Syracuse fell into the hands of the Romans under Marcellus (212 B. C.), by whom it was barbarously sacked and an immense booty carried off to Rome. From this time Syracuse, as well as the rest of Sicily, was but a subjugated Roman province, unscrupulously oppressed and plundered by that power for its own aggrandizement. The town at the time of its capture consisted of four distinct quarters—or five, if Epipolæ be included, as it no doubt was by those ancient writers who describe it as a *pentapolis*. Epipolæ, however, seems to have served rather as a citadel and fortress to defend the town on the N. W., and was probably never thickly inhabited. The four quarters proper were: (1) Ortygia, or the islet; (2) Achradine, occupying the eastern coast of the main island, N. of Ortygia; (3) Tyche, W. of Achradine; (4) Neapolis, S. of Tyche. The most important remains of ancient Syracuse are found on the main island, though some objects of interest are still to be seen in the modern town. Pop. (1893) 25,200. See Serradifalco, *Antichità di Sicilia*; Gregorovius, *Wanderjahre in Italien, Siciliana* (1872); Cavallari, *Sicilia artistica ed archeologica* (1889); Lupus, *Die Stadt Syrakus im Alterthum* (1887).

Syracuse: city; capital of Onondaga co., N. Y.; on Onondaga Lake, the Erie Canal, and the Del., Lack., and W., the N. Y. Cent. and Hud. Riv., the Rome, Water., and Ogdens., and the W. Shore railways; 147 $\frac{1}{4}$ miles W. by N. of Albany, and 150 $\frac{1}{4}$ miles E. of Buffalo (for location, see map of New York, ref. 4-F). It is at the foot of the Onondaga valley, though the southern part is embraced by hills on either side opening to the right and left, thus broadening the valley where it joins the city. There are highlands to the N. E. also which, with those on the S., are populated. The length of the city proper from N. to S. is about 4 miles; from E. to W. about 3 miles. Salina Street is the principal thoroughfare. The streets mainly cross at right angles; most of those otherwise laid out followed early Indian trails and wagon-roads. They contain so many trees that the city resembles a forest when seen from the adjoining hills. There are about 250 miles of streets, 52 miles of street-railway, 24 public parks (of which Burnet Park, of 100 acres, situated on the highlands W. of the city, is the chief), and 6 public squares. The city has a new water system, with its source at Skaneateles Lake, and with 90 miles of mains; it cost \$4,000,000. There are 34 newspapers (6 daily) and periodicals.

Public Buildings.—The U. S. Government building, the county court-house, and the city-hall, all built of limestone; the county clerk's and surrogate's offices; the First Pres-

byterian, St. Paul's, and St. Mary's churches; the Onondaga County and the Syracuse Savings-bank buildings; the Kirk building, the Granger block, the Bastable block, Dey's and McCarthy's buildings, and the Wieting block, are among the most imposing structures. The State Asylum for Feeble-minded Children and the buildings and grounds connected therewith are attractive and interesting to visitors. The Onondaga penitentiary and jail has room for about 300 prisoners, is situated within the city limits on elevated ground, and its inclosure embraces about 40 acres. The Onondaga County Orphan Asylum, St. Vincent de Paul Orphan Asylum, the House of Providence, House of the Good Shepherd (hospital), St. Joseph's Hospital, St. Ann's Maternity Hospital, Shelter for Fallen Women, Women's and Children's Hospital, Old Ladies' Home, German Hospital, Needlework Guild, Employment Society, Women's Union, Bureau of Labor and Charity, Women's Aid Society, Deaconesses' Home, and King's Daughters are the principal charitable institutions and organizations.

Churches and Schools.—There are 84 churches (with a total seating capacity of about 52,000), as follows: Presbyterian, 9; Baptist, 8; Methodist Episcopal, 20; Protestant Episcopal, 7; Roman Catholic, 11; Lutheran, 7; Congregational, 5; Evangelical, 4; Jewish, 7; Unitarian, Universalist, Reformed, Disciples, Independent, and Scientists, each 1. The Y. M. C. A. owns the large and commodious building it occupies, together with its music-hall and athletic rooms. The SYRACUSE UNIVERSITY (q. v.) leads the educational institutions. The public schools are 31 in number, including the High School, and all are built of brick. The enrollment is over 16,000; average attendance, over 12,000; annual cost of maintenance, over \$303,400; number of teachers, 320. The City Library, now independent of the board of education, has about 26,000 volumes, and occupies a city building. Keble School, which, with several others, has an attendance of about 300 pupils, is the principal private school.

Finance and Banking.—The assessed valuation is: real estate, \$44,827,180; personal, \$3,838,205—total, \$48,665,385; receipts and expenditures, about \$1,000,000; bonded indebtedness, \$5,056,500. There are 9 commercial banks, with an aggregate capital of \$1,705,000 and surplus of \$1,100,000; 2 savings-banks, with assets of \$19,000,000 and surplus of \$2,110,000; and 8 national savings and loan associations, with aggregate assets of about \$3,500,000.

Business Interests.—The manufacturing interests are extensive and cover a wide range of products. Iron and steel are extensively worked in various forms. Salt is no longer an important factor. The State took possession of the salt-springs in 1797; since then 361,200,742 bush. of fine and coarse salt have been produced. The largest quantity made in any year was 9,053,874 bush. in 1862; the smallest, 23,474, in 1797. Competition at home and abroad, with a low tariff aiding the latter, has nearly ruined the industry. At one time the investments were valued at \$14,000,000; now they are scarcely worth \$500,000. There are in all 245 incorporated manufacturing companies, of which one, making soda-ash, is the principal. In 1890 over \$17,000,000 capital was invested in 1,175 establishments; about 15,500 persons were employed, to whom nearly \$7,500,000 was paid in wages; material costing over \$12,000,000 was used in manufacturing; and the output of the manufactories had a value of over \$25,500,000.

History.—Syracuse was settled in 1797, and was known first as Bogardus Corners; afterward as Milan, South Salina, Cossitt's Corners, Corinth, and in 1824 Syracuse. In 1826 the village was incorporated; in 1847 the rival villages of Syracuse and Salina were brought under a city incorporation. The Jesuits, in 1654, were the first to visit the locality then inhabited by Indians, a remnant of 425 of whom now occupy a reservation 6 miles S. of the city, and 6 miles square. Pop. (1880) 51,792; (1890) 88,143; (1892) State census, 91,944; (1895) estimated, 127,089. DWIGHT H. BRUCE.

Syracuse University: a coeducational institution at Syracuse, N. Y.; founded in the year 1848, but located at Lima, N. Y., and known as Genesee College until 1871, when it was removed to Syracuse. The removal was determined by a great convention held in Syracuse in Feb., 1870. The most prominent citizens of the city aided in its new founding, and the city gave \$100,000 as its contribution. The first chancellor, Alexander Winchell, LL. D., was inaugurated Feb. 13, 1873. He was succeeded in 1874 by E. O. Haven, D. D., LL. D., he by C. N. Sims, D. D., in 1880.

and the present incumbent, James H. Day, S. T. D., entered upon his duties in Apr. 1894. The campus comprises 50 acres; the principal buildings are the Hall of Languages (1890), the Hadden observatory, the John Cresson Memorial College, containing the college of fine arts, the library building, containing the famous library formerly the property of the historian Von Hanne, and the Y. M. C. A. hall and gymnasium. The athletic field is one of the finest in the state. The medical college building is near the center of the city. The college was removed from Geneva in 1851. A college of law was opened in 1895. The number of students has steadily increased. The roll for 1894-95 showed 887. The faculty numbers 70. The institution has enjoyed a healthy growth and expansion in every department. The value of grounds and buildings is \$457,000, and the endowment fund is \$760,000, with a debt of less than \$100,000. The volumes (including pamphlets) in the library number 54,743. F. S. MALLORY.

Syr-Darya, Syr-Daria, or Sir-Daria, *sir-dar'ya*, (Pers. *Jaxartes*, Arab. *Sihun*); the principal river of Russian Turkistan. It rises in the Tien-Shan in a glacier at the height of 15,000 feet; flows first W. passing through mountain valleys, and through several unexplored gorges, receiving all its affluents; is largest opposite Khojend, where it passes out on the plains; gives off a few branches and many irrigation canals, and is decreased by evaporation, until it reaches the Aral Sea, where it is only a half or a third of the size it has at Khojend. It is frozen three or four months a year, is in flood in late spring and early summer, and is unsuitable for navigation because of its shallowness and changeable channel, and the lack along its banks of fuel. Length, 1,250 miles; area of basin, 120,000 sq. miles. Harsdollar and Strahlen describe it as a great river flowing into the Caspian, and the ancient belt between the Aral and Caspian can yet be traced. MARK W. HARRINGTON.

Syr-Darya: province of Russian Turkistan; on the middle and lower course of the Syr-Darya river, S. of the Tien-Shan, W. of Semirechensk, and S. of Akmoinsk. Area, 104,566 sq. miles. Pop. (1890) 1,214,300, mostly Kirghiz and Sarts, and 60,000 Russians, of whom 15,000 are military, 61,900 peasants, 4,000 small merchants, and the remainder officials, clergy, etc. Russia made an especial effort to colonize this province, and in 1899 there were forty-seven colonies containing 16,000 persons. The country is chiefly steppes, deserts, and marshes, but contains some forests near the streams, and much of the land is very fertile when irrigated. Capital, Tashkent. M. W. H.

Syren, or Sirene: See *Acoustics* (Length of Sound-waves).

Syria [= Lat. = Gr. *Συρία*, deriv. of *Σέρος*, *Séros*, Syrian, a Syrian; etymologically an abbreviation of *Assyria*. See *Assyria*. (Heb. *Arām*; Arab. *ash-Shām*; Turk. *Suriyan*)]; a vilayet of the Ottoman empire in Asia Minor; bounded N. by the vilayet of Aleppo, E. and S. by the Syrian and Arabian deserts, W. by the Mediterranean (see map of Turkey, ref. 7-H). In a less restricted sense, Syria comprises also the larger part of the vilayet of Aleppo, thus including the territory bounded N. by Asia Minor, from which it is separated by the Akma Dagh (Antanus Mountains) E. by the Euphrates, and S. by the Arabian Desert. Its length on the W. is coterminous with the eastern shore of the Mediterranean Sea. Its situation may be roughly indicated as between 37° and 31° N. lat. and 34° and 41° E. lon. It comprises the historical divisions of Syria proper, PHOENICIA, COELE-SYRIA, and PALESTINE (q. v.).

Physical Features.—Two systems of mountain ranges, LABRAN and ANTI-LIBANUS (q. v.), connected with the Taurus Mountains, run parallel southward, enclosing a long valley of varying breadth and depth, COELE-SYRIA, and losing themselves in the S. in the rocky plateaus of the Arabian Desert. The three chief rivers of Syria are the ORONTES and JORDAN (q. v.) and the LEANES (Litany), none of them over 250 miles in length. There are also a score of still smaller rivers and many river-beds, filled by rushing torrents in spring but dry in summer. The valley of COELE-SYRIA narrows in the south in a gorge through which the Jordan forces its way into the Lake of Merom (El Huleh). There it is on a level with the Mediterranean, but at the Lake of Hinnom it is 650 feet and at the Dead Sea 1,300 below it. More, as in many other regions, the country has a strongly marked volcanic aspect, and throughout Syria earthquakes are frequent. It is a peculiar fact that they occur usually in summer and very rarely in winter. One (1759) caused the

death of more than 20,000 persons; another (1778) destroyed Aleppo; those of 1782, 1819, 1822, 1837, and 1873 were notable. Wherever the supply of water is sufficient the soil, generally of a light and sandy character, proves very productive. Most plants of temperate and tropical climates grow luxuriantly. Navarichius, at certain seasons almost the entire country, and at all seasons a large part of it, presents a barren and desolate appearance. This is in great part due to annual drouths. Summer rains are rare. The climate is patchy, and the heat oppressive even in the elevated regions, the thermometer often indicating above 100° F. The average of the country is the humid, Aluvial, however, the misfortune of Syria has been its geographical position, rendering it the battle-field of races and religions.

Natural Products.—*Flora and Fauna*.—The mountainsides are covered with pine, fir, and oak. Cedars are still found in Lebanon; laurel groves are frequent in the valleys; on the tablelands are dwarf-oaks which yield excellent fuel-wood. Extensive forests are rare. Farming tools and implements of all sorts, as well as the system of cultivation and handicraft, are of the simplest. The common cereals are wheat, rye, and barley; rice, durum, sesame, lentils, and beans are raised. Cotton, hemp, mulberry, indigo, molins, cucumbers, and artichokes are extensively cultivated. The tobacco along the coast is of excellent quality. Plantations of fig, orange, lemon, mulberry, peach, pomegranate, and almond, and the vineyards yield excellent returns. The coffee-plant has been introduced at Latakia, the sugar-cane at Beyroul, and Damascus is surrounded by orchards and gardens. All the domestic animals of Europe are found in Syria, as is also the camel. Asses, horses, horned cattle, goats with fine hair, sheep, both broad-tailed and of fine fleeces, are numerous. The wild animals are jackals, hyenas, antelopes, the Syrian bear, wolves, and especially wild boar, deer, and wild buffalo. The silk-worm is extensively reared. Mining is hardly carried on; but bitumen, coal, iron, salt, and sulphur are found.

Population.—There are no reliable statistics as to population. It is probably not far from 4,500,000, and is made up of heterogeneous races, peoples of Semitic origin predominating. Arabic is the generally spoken language. The old Syriac or Aramaic is heard only in certain localities. Along the coast Greek is generally understood, and French much employed by the higher classes. Tribal divisions are rather on the score of religion than origin or race. The country swarms with sects, Musliman, Jewish, and Christian, equally jealous and intolerant. The Druses (60,000), Maronites (60,000), Lemalis (6,000), Yezidis (25,000), Nusairis or Nusayris (60,000), Chaldeans or Nestorians (40,000), Syrians or Jacobites (10,000), and Maronites (452,000) are the more prominent of the best known. Though in general these peoples are quiet, hospitable, and kindly, yet outbreaks of fanaticism are frequent, not only on account of their detestation of each other's belief, but through the intrigues of foreign powers. Such were the massacres of 1841, 1845, and 1869. There is no question that the condition of the people has bettered in many respects since 1873. Education, though in a backward state, has made substantial progress. This improvement is due in large measure to the labors of the Roman Catholic and Protestant missionaries, and especially to the wide and active influence exerted by the Syrian Protestant College at Beyroul. The chief cities, with populations, are as follows: Damascus, 200,000; Aleppo, 120,000; Beyroul, 100,000; Jerusalem, 41,655; Hama, 55,000.

History.—The earliest known inhabitants of Syria were Semites of various branches, living in separate social organizations. Such were the Canaanites, Phoenicians, Arameans, the latter of whom held Damascus and ruled to the Euphrates. Such, too, were the Hebrews. Practically all Syria, except Phoenicia, became subject to the Hebrew monarchy under David. When, on the death of Solomon, the Hebrew empire divided into the two kingdoms of Judah and Israel, an independent Aramaean monarchy under Hazan was set up at Damascus. Its kings conquered Northern and Central Syria. Tiglath-Pileser, King of Assyria, subdued this state, capturing Damascus (740 B. C.), and likewise Israel (720 B. C.). Judah was conquered by Nebuchadnezzar, the King of Babylon, in 587 B. C. Syria passed from the Assyrians to the Babylonians, then to the Medes, then to the Persians, and after the battle of Issus (333 B. C.) to Alexander and the Greeks. During these transitions many non-Semitic elements were introduced into the population. On the death of Alexander the Seleucids founded a Syrian empire which they ruled from 301 to 64 B. C. Antioch, built by Seleucus I.

(301-281 B. C.), was their capital. For centuries it was the largest and most brilliant city of the East, and was further influential through the civilization therein developed. The Syrian empire at the height of its prosperity rivaled in extent that of Alexander. Antiochus III., the Great (223-187 B. C.), was a most formidable enemy to Rome. Antiochus XIII. (69-65) was overthrown by Pompey, who made Syria a proconsular Roman province (64 B. C.). It continued part of the Roman and then of the Byzantine empire, but (635-638) was gradually conquered by the Muslims. Damascus was made the capital of Syria in 654; under the Omniad dynasty of caliphs it continued the capital of the entire Mussulman empire (661-752). The Abbassid caliphs, hating all that was associated with their Omniad predecessors, degraded Syria to the rank of a province and removed the capital to the newly founded Bagdad. Distracted by rebellions and by frequent wars between the caliphs and the Byzantine empire, the condition of Syria was deplorable during the three subsequent centuries, till it fell under the humane sway of the Seljuk sultan Malek Shah (1073-93). Next the crusaders deluged the country, and the succeeding two centuries—from 1099, when the Christian kingdom of Jerusalem was set up, until 1291, when Acre, the last Christian stronghold in Syria, was retaken by the Muslims—formed the most disastrous and destructive period Syria has ever known. From that time, except during the invasions of Tamerlane and his successors, Syria was ruled by the Mameluke sultans of Egypt until 1516, when it was conquered by Sultan Selim I. From 1832 to 1841 it was governed by Ibrahim Pasha under the authority of his father, Mehemet Ali of Egypt. With the exception of this brief period it has, since the days of Sultan Selim, formed an integral part of the Ottoman empire.

EDWIN A. GROSVENOR.

Syriac Language: See ARAMAIC.

Syriac Literature: the literary productions of the Syriac Church. Its rise is lost in the first centuries of the Christian era. It is at its best from the fourth to the seventh centuries, when Arab dominion begins to impose its language upon Syria and Mesopotamia. From the tenth century on Syriac is only a literary tongue. Productiveness in that language dies out in the thirteenth century, just after a short period of revived glory. From the sixth century the split in the Eastern Church into Nestorians and Jacobites makes itself felt in the literature. It is probable that at one time there existed a heathen Syriac literature, but none of it has come down to us. The first writer in Syriac (Bardanes, the last Gnostic) was a convert to Christianity. The translation into Syriac of the Bible (see PESHITO) and of Greek theological and secular works laid the foundation upon which later scholars built. Learning had found a home in the great schools of Mesopotamia—Edessa (destroyed by the Persians in 489), Nisibis, Māchōzē, Dōr-Kōnī, Jerablīs, Mosul, etc. The literature is largely a theological one, and of importance because of the many translations it contains.

In these schools the study of the Bible was the chief interest. It was necessary to fix accurately the wording and the pronunciation of the more difficult expressions in both the Old and New Testament. This Masoretic work seems to have centered in certain convents—e. g. in the Jacobite one of Karkaftha, near Rās'a'in, whence the best of such MSS. come (Martin, *La Massore chez les Syriens*, Paris, 1880). With this there went hand in hand the writing of commentaries upon the Bible, which were, of course, more theological than critical. The great Syrian Father Ephraem (d. 373) wrote commentaries upon both Testaments and upon the Diatessaron of Tatian. Among Nestorians were Hannānā (d. 607), a determined opponent to the exegesis of Theodore of Mopsuestia; Bābāi the Elder (610); Elias of Merv; Ishō'dād of Merv (852). The Jacobites have names of greater prominence—Jacob of Edessa (640-708); Daniel of Salāh (eighth century); Moses bar Kēphā (813-903); and Daniel bar Salibi (d. 1171), Bishop of Mar'ash. More like the Jewish Midrash and the pseudepigraphic literature are such compilations upon biblical history as the *Cave of Treasures* (ed. Bezold, 1883-88), *The Book of the Bee* (ed.

Budge, Oxford, 1886). Of purely theological interest are the collections of church and monastic rules (*Canons*) which were formulated at various times—those of the Jacobite Church by Jacob of Edessa and Gregory Bar 'Ebhriyā, those of the Nestorian by Abbdishō. The great schism in the Church has called forth a large polemical literature. One of the best apologies on the Nestorian side was written by Elias of Nisibis (b. 975), ed. by Horst, Colmar, 1886; while the Monophysites were defended by that elegant writer Philoxenus of Mabug (485). The homily was a favorite form of religious exhortation. A large number of such homilies have come down to us from Ephraem (ed. Lamy, 3 vols., Mechlin, 1882-86); Ibas (435); Jacob of Nisibis, called Afraates the Persian Sage (d. 338), trans. into German by Bert (Leipzig, 1888); Philoxenus (ed. Budge, 1893); and Jacob of Lerug (503), who is said to have composed as many as 760.

Poetry was also known in the service of the Church, though even historical, philosophical, and grammatical works were put into verse. Bardanes (b. 154) is the first poet; he is followed by Ephraem, Balai (431), Cyrillōnā, Isaac of Antioch (d. 460), Narsai (489), and the Nestorians George of Mosul (d. 987), George Warda (1225), whose hymns are largely used in the Nestorian ritual, and Chamis bar Kardāhē of Arbel. Syriac poetry can not lay claim to great originality. Its system of meter is based upon two principles—the rhythmic sequence of accented or unaccented syllables, the one the arsis, the other the thesis of the verse, and the counting of the syllables. See Grimme, *Der Strophenbau in den Gedichten Ephr. des Syrers* (Freiburg, 1893).

Syriac literature is rich in historical works which throw much light upon the ecclesiastical and political history of the Christian Church in Mesopotamia. The *Didascalia* and *Constitutiones Apostolorum*, the legends of Abgar and the apostle Addai, and the Edessenian chronicle (Hallier, *Unters. über die Ed. Chronik*, 1892) are of prime importance (Duval, *Hist. d'Édesse*, 1892). The ancient martyrologies (re-edited by Bedjān, 4 vols., Paris, 1890-95) are full of interesting material, as are also the Nisibene hymns of Ephraem, the poems of Isaac of Antioch, and the historical romance dealing with the persecutions under Julian the Apostate (*Zeit. der Deutsch. Morgenl. Gesellschaft* 28, 263). Other historical works deal largely with the war between Rome and Persia. An anonymous Monophysite has turned the ecclesiastical history of Zacharias Rhetor of Mitylene (560) into Syriac, and united it with other works. Very full and accurate is the ecclesiastical history of John of Ephesus (b. 505) in three parts. Other writers are Simeon Barkāyā (591); George, Bishop of the Arabs (686); Jacob of Edessa, who finished in 692 a continuation of the chronicle of Eusebius; Dionysius of Tel Mahrē (817); Thomas of Marga (832), author of a monastic history (ed. Budge, 1893); Elias bar Shināyā; Michael (1163), whose work exists in an Armenian translation, etc.

Translations were made from the Greek at a very early time—e. g. the *Recognitiones* of Clement; the *Apology of Aristides* (ed. Harris, Cambridge, 1891); the discourses of Titus of Bostra; the *Theophania* of Eusebius; the commentaries of Theodore of Mopsuestia; the *Geoponica* (ed. Lagarde, 1860); the *Physiologus*; the works of Homer; the collection of *Leges Seculares* (ed. Sachau, 1880); the fables of Aesop; the medical works of Galen and Hippocrates. Many of these are useful for text-critical purposes; some have not been preserved in the original Greek. Among translators known by name are Ma'na (430), Moses of Agghel (550), Athanasius II. (684). A great many of the works of Aristotle were also translated, especially the *Organon* (Gottlieb, *Hebraica*, ix., 166). Probus (about 450), George of the Arabs, Sergius of Rās'a'in (about 540), Jacob of Edessa, and Honain (873) are the leaders in this work. From the Syriac texts were translated into Arabic, and from Arabic into the languages of Europe. The old Sanskrit stories of Kalilag and Damnag, of Sindban, and the history of Alexander the Great were done into Syriac from the Pahlavi. The translations of Aristotle formed the natural starting-point for all philosophical study, but the Syrians hardly got beyond commenting and excerpting their Greek master. To the names already mentioned may be added those of Paul of Persia (575), Severus Sabocht (d. 631), Mār Abhā II. (740), Antonius Rhetor, Moses bar Kēphā (b. 813), Bazūdā, and Severus bar Shakkō (d. 1241). See Renan, *De Phil. Peripat. apud Syros* (Paris, 1852).

The only non-theological science that was really cultivated was that of philology. Syriac lexicography had its begin-

ing in the necessity of determining accurately the meaning of words in the Bible and of the many Greek expressions which had been taken over into the translation of other works. Collections of such explanations were made by Ananias, Hama, Bar Seredwan (fourth century), but especially by Bar Jil (940) and Bar Habbil (961), where the definitions are in Syriac and Arabic. In grammar the starting-point was Aristotle and the Syriac translation of the *Topics* of Dionysius Thrac (Guthrie), *Topics in Syriac Grammar*, Berlin, 1907, p. 6; Marx, *Hebr. ar. u. syriac grammatica* (1890). To later times the influence of the grammatical studies of the Arabs was also felt. The chief grammarians are Joseph Hazzay, Jacob of Edessa, Elias of Tishrin (1028), Elias of Nisibis, Joseph bar Malkon (1300), John bar Zafil (thirteenth century), and Severus bar Shakkai. Other branches of science were hardly cultivated except for the writing of such compendia as the *Hexameron* of Jacob of Edessa, Emmael (966), *Maat bar Kephai* (fifteenth), *Habeshah*, vol. 63; Hlel, *Etudes sur l'Heb. de Jacques d'Edessa*, Helsingfors, 1902. Travel has published some interesting Syriac works on astronomy (Bertholet, *Les Chénies au Moyen Age*, II, Paris, 1906).

This short account may be fitly closed with a reference to two lights which illuminated the last days of Syrian literature. Abduh al. (1818), the Nestorian, was the first to attempt a history of his national literature (*Catalogue Liberaire*, in *Annuaire Bibl. Orient.*, III, 1). In his *Bibliotheca de Edessa* he attempted to imitate the *Maknûs* of Hariri (ed. Cardahi, Beyrouth, 1860). He also wrote a work on theology (*The Pearl*) and a collection of canons (*Mo' Script. Yell. Nova Coll.*, x.). Undoubtedly the most learned of all the Syriac writers was Gregory bar 'Ebrayâ (Bar Hebraeus, Abul Faraj), b. 1293; d. 1346. There is hardly a province of literary activity which he did not cultivate. He wrote the most comprehensive native grammar (ed. Martin, 1872), and the most useful native commentary upon the Peshitta (*Nurehaneh de Nureh*). That he had some acquaintance with physical sciences is shown in his *Lamp of the Sanctuary*, a compendium of all sciences in his *Ascent of the Mind*, a treatise on astronomy and cosmography; and in his translation of Dioscorides's *Dei Saporis*, his commentary on works of Galen, and in a medical work of his own. He wrote a work on ethics on the life of an ascetic (*Book of the Dove*), and a commentary on the mystical *Book of Isidore*. His historical writings are very valuable. His *History of the World* has been re-edited by Bodjan (Paris, 1906); his church chronicle by Abelos and Lamy (Louvain, 1872-77). He also made an Arabic recension of his *History of the World*. Bar Ebrayâ was a poet of some prominence. A number of his poems have been edited by A. Barhaili (Rome, 1877). See Nöldeke, *Sketches from Eastern History* (Lamkin, 1892).

See W. Wright, *A Short History of Syriac Literature* (London, 1893). R. Graffin has begun the publication of a complete *Patrologia Syriaca*, the first volume of which contains *Apocrypha Scripturae Perse Demonstrationes* (Paris, 1904).

RICHARD GUTHRIE.

Syrian Rite. See UNITED SYRIANS.

Syringa [Mod. Lat., from Gr. *σῦρις*, *σῦρις*, a shepherd's pipe, tube]; a genus of Old World shrubs of the family *Oleaceae*, to which the lilacs belong. (See LILAC.) Popularly, the beautiful shrub *Philadelphus coronatus*, of the family *Hamamelidaceae*, and often seen in gardens, is called sweet syringa. It is a native of Japan; its cream-colored, fragrant flowers somewhat resemble orange-blossoms, whence another popular name of mock orange.

Revised by CHARLES E. BENNEY.

Syringe [from Gr. *σῦρις*, *σῦρις*, tube, pipe, lit., shepherd's pipe]: an instrument ideal in principle with the ordinary suction-pump. A vacuum is formed, either by means of a piston or a compressible chamber of India-rubber, fitted with suitable valves. Water or some other fluid then rushes in and fills the vacuum, and a second application of pressure causes a jet of the contained liquid to be thrown out. The syringe is of many forms, chiefly employed in surgery, in horticulture, etc.

Syro-Chaldeans and Syro-Orientalis. See CHALDEAN CHRISTIANS.

Syrus. See SYRA.

Syr'ia, Major and Minor [Lat., Greater and Lesser Syria]: the ancient names of the two large halves, or rather of the two opposite angles (E. and W.) of the great almost rect-

angular continent in the east bounded by the Mediterranean, of which the angles are the wastes of Taurus and Tigris. They are now called respectively the Gulf of Suez and the Gulf of Aden. They are shallow and dangerous to navigation on account of quicksands and the uncertainty of the tides.

Revised by J. H. S. STOKLEY.

Syrus, Ponticus. See PONTICUS SYRUS.

Syran's town in the government of Pskovsk, Russia, on the Syran near its influx into the Volga (see map of Russia, vol. 6-61), and in the center of a very fertile district, from which it exports large quantities of grain. Pop. (1889) 30,442.

Syrtakia. See HELLY.

Szabadka, so called (Germ., *Heuss Theresopolis*); town in the county of Bacs, Southern Hungary, on Lake Palud (see map of Austria-Hungary, vol. 7-11). It has manufactures of iron and leather, important cultivation of tobacco and breeding of cattle, and a brisk trade in horses, cattle, sheep, wool, and hides. It consists of the town proper and sixteen suburbs, and is rather indifferently built, though it contains several handsome buildings, such as the Church of St. Theresa, the beautiful Greek church, the town-house, the barracks, etc. Pop. (1890) 73,396.

Revised by M. W. HARRINGTON.

Szalay, soloj, LAZAR: historian; b. at Buda, Hungary, Apr. 18, 1813; studied at the University of Pesth, and was admitted to the bar in 1831; devoted himself to history, jurisprudence, and politics; became editor of various leading reform papers, and published a collection of political essays in 1847, and of political biographies 1847-50; was the most prominent member of the commission for the revision of the Hungarian penal code, a work which earned great admiration outside Hungary; succeeded Kossuth as editor-in-chief of the *Pesti Hírlap* in 1844; was sent as ambassador in 1845 to the provisional government of Germany in Frankfurt; resided subsequently in London and Switzerland, occupied with historical studies; returned to Hungary in 1861. D. at Salzburg, July 17, 1903. Among his works are a *History of Hungary* (8 vols., 1850-64); *Kossuth's Miklós* (2 vols., 1863-66); and *The Book of Natanson*, a collection of political biographies. F. M. COLBY.

Szarvas, ser'vash; town of Hungary, on the Körös (80 miles S. E. of Budapest (see map of Austria-Hungary, vol. 7-1)). It was formerly fortified, but its fortifications have fallen into decay, and it derives its importance mostly from its trade in grain and cattle. It suffered severely during the sieges of 1565 and 1685. The surrounding country is swampy and marshy, but famous for its extensive bee-culture. Pop. (1890) 24,300.

Revised by M. W. HARRINGTON.

Szatmar-Nemet, sot-mar-nó-met; town of Hungary, on the Szamos; 68 miles by rail N. E. of Debrecze (see map of Austria-Hungary, vol. 6-1). It has a Roman Catholic cathedral, and has extensive manufactures of shawls, a kind of brandy distilled from plums. The town was formed by the union of Szatmar and Nemet in 1715. Pop. (1890) 21,218.

Széchenyi, szé'chen-yi, IETVÁN, Count; Hungarian statesman; b. in Vienna, Sept. 21, 1792, of an old and celebrated Hungarian family; served in the Austrian wars with Napoleon, but retired from the army in 1825, and devoted himself wholly to the material and spiritual development of his native country. He took a prominent part in the foundation of the Hungarian Academy of Sciences, of the first Hungarian theater, of the conservatory of music in Pesth, etc., and in the erection of the great bridge across the Danube at Pesth, in the regulation of the course of the Danube through the Iron Gates, in the establishment of steam-navigation on the Danube and the Theiss, etc. In political matters he desired reform, not revolution. He held that the progress of Hungary could not be effected unless by the aristocracy and in alliance with Austria, and he consequently opposed Kossuth very strongly. Nevertheless, in 1848 he consented to be a member of the Batthyány-Kossuth ministry, but on the outbreak of the war with Austria he became insane, and was taken to the asylum at Békés, near Vienna. Here he nearly recovered, but in Mar., 1860, the Austrian police, suspecting him of being the author of a political pamphlet which criticized the Government very severely, undertook a search of his rooms and papers, and this excited him so violently that he relapsed, and killed himself Apr. 6, 1860. He was the author of several spirited pamphlets.

Revised by F. M. COLBY.

Sze-chuen, or **Ssü-chuen**, se'chwān' [literally, four streams]: the largest province of China, bounded N. by Kansuh and Shensi, E. by Hupeh, S. by Kwei-chow and Yunnan, and W. by Tibet; area, 166,800 geographical square miles, or 220,000 statute square miles. The portion lying W. of the river Min (an important affluent of the Yang-tse, regarded by some as the upper course of the Yang-tse itself) is little known. It has an area of 120,000 sq. miles, is exceedingly mountainous, and forms part of the great mountain lands of Central Asia. With the exception of some small inclosures it is little populated, is almost uncultivated, and of inferior importance as regards the value of its products. Here are found several Tibetan and aboriginal tribes, such as the *Man-tse* (a people considered by the Chinese to be the remnants of the ancient occupants and rulers of the province), the *Si-fan*, who are divided into numerous tribes, each with its own chieftain, and the *Lolos*, who are practically independent, and from whose frequent raids the Chinese settlers suffer greatly.

The eastern portion, which may be regarded as Sze-chuen proper, has been described by Baron von Richthofen as a large triangular-shaped basin surrounded by mountains (mostly of Silurian and Devonian age), some of which rise above the snow-line, and all of which are difficult to cross. The basin he calls the Red Basin, from the accumulations of red clayey sandstones and sandy clays which are found in it. The summit lines within the basin are nearly at a level with one another, and would if connected represent an undulating plain, 3,000 to 4,000 feet above sea-level, but owing to the fact that the bed of the Yang-tse is 1,500 feet or more below the level of the plain, and that rocks of the Red Basin are soft and easily destructible, the rivers have eroded deep channels, and converted the entire basin into a hilly country. With the exception of the plain of Ching-tu, Sze-chuen contains no level ground worth speaking of.

Sze-chuen can be approached from the E. by only two routes: (1) by the Yang-tse, up whose gorges boats and junks (never exceeding 70 tons burden) are dragged slowly and at great expense and risk, and (2) by the "Great North Road" over the mountains from Si-ngan-foo. Communication within the province is everywhere difficult (except in the plain of Ching-tu), and is kept up chiefly by utilizing the affluents of the Yang-tse and their numerous branches. Several pack-roads, paved with flagstones, have been constructed, and steps cut in the rocks at very steep places. That which connects Ch'ung-K'ing with Ching-tu-foo is a good example. The sedan-chair is the commonest mode of conveyance used by travelers, while goods are transported by coolies. Beasts of burden are little used.

Coal is found in Sze-chuen, but is not mined extensively. The manufacture of iron from its ores is perhaps the most generally distributed industry of the province. Salt is extensively made from brine raised from wells ranging in depth from 700 to 3,000 feet, and evaporated in some places by coal, but in many by natural gas. Petroleum is plentiful, but is not utilized. The value of the salt produced annually is about \$63,000,000. On this the province receives a tax of \$3,150,000, while the province of Hupeh, which levies a tax of 18 cash a catty, takes \$2,100,000. The other chief products of the province are silk, opium, insect wax (see PEH-LA), tobacco (which is of excellent quality, and is used by the natives in leaves rolled up in the shape of cigars), tea (only green and of inferior quality), and t'ung oil.

The inhabitants are, as a rule, gentle in character and refined in manners, and are both industrious and prosperous. All the great commerce of the province, however, is in the hands of men from Shensi and Kiangsi, and banking and pawnbroking are controlled by men from Shansi. The population is about 67,000,000. CH'UNG-K'ING (q. v.) is the only river-port opened to foreign residence and trade, but missionaries, both Protestant and Roman Catholic, are found in many places. The capital is CHING-TU (q. v.). See Baber's

Travels and Researches in Western China (London, 1882); Hosie's *Three Years in Western China* (London and New York, 1890); and Little's *Through the Yang-tse Gorges* (London, 1887). R. LILLEY.

Szegedin, sech-ed-ee'n': city; in Hungary, at the junction of the Maros with the Theiss; 118 miles by rail S. E. of Budapest; connected by a bridge of boats with Neu-Szegedin on the opposite bank (see map of Austria-Hungary, ref. 7-H). The houses are generally only one story high, with thatched roofs; the streets are broad, but mostly unpaved, and sometimes are rivers of mud. The old Turkish castle in the center of the town is the sole reminder that Szegedin was once an important fortress. In 1879 the town, with the surrounding country, was submerged by inundation; almost half the houses were destroyed, and nearly 2,000 persons perished from drowning or exposure. Soda, soap, and cloth are manufactured on a large scale, and an active trade is carried on in corn, wine, tobacco, salt, and lumber. At its annual fairs vast exchanges of goods take place. The town is famous for its floating mills and river-boats. The Hungarians were defeated here by the Austrians (Aug. 3, 1849). Pop. (1890) 85,569. E. A. GROSVENOR.

Sze-ma (or **Ssü-ma**) **Kwang**: one of the most prominent statesmen and writers of China, and as a historian second only to Sze-ma Ts'ien; b. in 1009; d. 1086. He was remarkable for precocious intelligence, and a story is told that illustrates his presence of mind and resourcefulness even when a boy. A playmate, having fallen into one of the large earthenware vessels in which the Chinese keep tame fish, was on the point of drowning, when Kwang dashed a large stone against the jar and broke it, thus letting the water escape and saving the life of his companion. He was employed at an early age in Government office, and rose to high rank in the ministry. He is noted, first, for his strenuous and successful opposition to the reforms advocated by his contemporary Wang An-Shih, usually called "the Innovator"; and, second, for his great historical work, in 294 books, *The Comprehensive Mirror of History*, on which he spent the leisure of nineteen years. It covers a period extending from the beginning of the fourth century B. C. to 960 A. D. He was also the author of several important dictionaries. R. L.

Sze-ma (or **Ssü-ma**) **Ts'ien**: author of the first general history of China; b. at Lung-mün, in what is now the province of Honan, about 163 B. C. He early devoted himself to study, and at twenty entered upon an extended course of travel throughout the empire. After this he held several minor offices under the Government until 110 B. C., when he succeeded his father, Sze-ma T'an, as grand recorder and astronomer, and shortly thereafter entered upon the task of completing the great historical work begun by his father. This was finished in 91 B. C., and received the name of *Shih-ki*, or *Historical Records*. It extends from the beginning of the reign of Hwang-ti (B. C. 2697) to 104 B. C. It has become the model for all Chinese historical works, and is divided into five parts: (1) Imperial Records; (2) Chronological Tables; (3) Treatises on Rites, Music, Chronology, Astrology, Sacrificial Service, Watercourses, Weights and Measures, etc.; (4) Genealogical History of the Princes and Grandees; and (5) Narratives, or biographies, and accounts of foreign countries and their affairs. About the year 18 B. C. Sze-ma incurred the displeasure of the emperor, and was thrown into prison because of his defense of Gen. Li Ling, who having foolhardily advanced far into the territory of the Huns with a body of 5,000 foot-soldiers, had been overthrown, and then, afraid to face the wrath of the emperor, had surrendered. Sze-ma is also noted for reforming the calendar, and the chronology determined by him still obtains in China. He died in disgrace about 85 B. C. For a specimen of his writings, see Giles's *Gems of Chinese Literature* (London and Shanghai, 1884). R. L.

T

: the twentieth letter of the English alphabet.

Form.—The form T is inherited via the Roman alphabet from the early Greek T or + X X. The form of the Semitic original was that of a cross, + or X. It occupied the last or twenty-second place in the original alphabet adopted by the Greeks from the Phœnicians.

Name.—The Semitic name of the letter was *tau*, i. e. mark, cross, whence the Greek *ταυ*. The Latin phonetic name *te* passed through the French *té* into English as *te*, now pronounced like *tea*.

Sound.—It commonly denotes a voiceless dental (or alveolar) explosive formed by breaking a closure between the tongue-tip and the alveolar terrace back of the upper front teeth as in *tar*, or by effecting a check at the same point as in *rat*. Generally there is in the latter case an additional after-puff caused by again breaking the closure; thus in *art* the after-puff constitutes the only characterization of the sound. The same sound is denoted also by *th* in *Thames*, *Thomas*, *thyme*, *phthisis*, and by *(ed)* in preterites and participles, as *asked*, *rushed*. The letter *t* is silent in *hauiboy*, *hasten*, *listen*, *often*, etc., *bustle*, *thistle*, etc., *chestnut*, *Christmas*, *mortgage*, *bankruptcy*, *waistcoat*, *Matthew*; in the combination *ti* before vowels it often has the value of *sh* (*s*), as in *initial*, *action*, etc., but in *-sti-* it has the value of *tsh* (*tš*), as in *question*, *Christian*. In the combination *th* it represents a spirant, either voiceless, as in *thin*, or voiced, as in *then*.

Source.—The sound represents in Teutonic words an Indo-European *d*; cf. *ten*: Lat. *decem*; *tooth*: Lat. *dens*; *two*: Lat. *duo*; *heart*: Lat. *cor*, *cordis*; or when following *s*, *h*, or *f*, an Indo-European *t*, as in *stand*: Lat. *stare*; *night*: Lat. *nox*, *noctis*; *eight*: Lat. *octo*. Between *s* and *r* it is exrescent, i. e. a special development of Teutonic; cf. *stream*, Indo-European root *sreu-*, *sister* from *suesr-*, Lat. *soror*. It is also an exrescent product of Mod. Eng. after final *-s*, e. g. in *betwixt* < M. Eng. *betwix*; *against* < M. Eng. *ageines*.

Symbolism.—T = Tuesday, ton, Tullius; Ta = tantulum; Te = tellurium; Th. = Thursday, thorium; Ti = titanium; Tl = thallium. BENJ. IDE WHEELER.

Taafe, *taa'fe*, EDUARD, Count: Austrian statesman; b. in Prague, Feb. 24, 1833, of an Irish family; was educated with the Emperor Francis Joseph; entered the public service in 1857; became Austrian Minister of the Interior in 1867; Minister President in 1869 and again in 1879. The chief object of his policy has been to form a middle party which should unite conflicting nationalities and creeds. He has sought to increase the strength of the Slavic element in the empire. In 1893 he alienated the conservatives, the German liberals, and the Poles by his electoral reform measure, and was forced to resign Oct. 29. F. M. COLBY.

Tabasco: a southeastern state of Mexico, bounded N. by the Gulf of Mexico, E. by Campeche, S. E. by Guatemala, S. by Chiapas, and W. by Vera Cruz. Area, 9,844 sq. miles. The southern portion only is mountainous, the rest consists of extensive plains and low rolling lands bordering the river Grijalva and its tributary, the Usumacinta, both of which are navigable. There are extensive swamps and lagoons near the coast, much of the surface is covered with matted forest, and the roads, even in the most settled portions, are execrable. The climate is warm and damp; there is no true dry season, but rains are most copious from July to October and in December and January. The soil nearly everywhere is very fertile; besides the common crops of maize, etc., cacao and sugar-cane are raised, the former for exportation and the latter principally for the manufacture of rum. There are no mines of importance. In general, Tabasco is one of the least progressive of the Mexican states. Pop. (1893) estimated, 111,820. Capital, San Juan Bautista. HERBERT H. SMITH.

Tabasco River: See GRIJALVA.

Tabasheer [from Pers., Hind., and Arab. *tābāshīr*; cf. Sanskr. *tavakshira*]: a white variety of opal obtained from

the hollow stems of certain bamboos. It appears to be the product of an exudation of the siliceous sap of the plant into its internal cavity, caused by disease or injury of the plant. It is very light, brittle, porous, and has hygrometric properties. There are several varieties. The transparent kinds have a very low refractive power. The Hindus ascribe to it valuable medicinal virtues.

Tabatin'ga: a town of the state of Amazonas, Brazil; on the north side of the river Amazon, close to the frontier of Peru (see map of South America, ref. 3-C). It is the terminal port for the regular Brazilian steamboat lines, and the point of departure for small steamers which ply on the Peruvian rivers; there is a growing trade, especially in rubber. Ocean steamships have ascended to this point, nearly 2,000 miles. Pop. about 3,000. H. H. S.

Tab'ernacle [via O. Fr. from Lat. *taberna'culum*, tent, (in Late Lat.) tabernacle, dimin. of *taber'na*, shed, booth, shop, used as transl. of Heb. *mišh'kān*, dwelling-place, tent, tabernacle, or, 'ōhel, tent, tabernacle]: a tent erected, under minute divine directions (Exod. xxv.-xl.), by the Israelites at Mt. Sinai, and carried with them into the Holy Land. It was set up at Gilgal (Joshua iv. 19), then at Shiloh (Joshua xviii. 1), next at Nob (1 Sam. xxi. 1), then at Gibeon, where it is last mentioned (1 Chron. xxi. 29). It was designed as the place where God should especially manifest his presence to his people, and where they should offer to him their sacrificial worship, and was replaced by Solomon's temple which exactly doubled its dimensions. It was a rectangle 45 feet long and 15 broad and 15 high. Its two sides and western end—the eastern end was left open—were made of acacia boards placed on end in silver sockets, and bound together by rods overlaid with gold; and the frame was covered with (1) linen, on which was embroidery representing cherubim; (2) black goats'-hair cloth; (3) rams' skins dyed red; (4) seals' skins (or porpoise-skins). It consisted of two adjoining rooms, with an outer court surrounding both. The inner room, which was an exact cube, contained the ark of the covenant, with its contents; over this were the figures of two cherubim, and between them the Shekinah. The only access to this room, which was called "the holy place," or "the holy of holies," "the holiest of all," "the second tabernacle" (Heb. ix. 3, 7), was from the outer room, which was called "the holy place," also "the sanctuary," "the first tabernacle" (Heb. ix. 6), of the same width and height, but just twice the length. Between them hung a veil, or rather double curtain, which was passed only by the high priest, and by him only on one day of the year, the great day of atonement. In the outer room was the golden censer, the golden altar on which incense was burned every morning and evening, the table of shew-bread, on which were twelve loaves of bread, replaced each week, and the golden candlestick, the lamps of which were trimmed every morning and lighted every evening. Into this the high priest and the priests entered daily, in the course of their regular ministrations, but no others. The entrance was at the eastern end from the court in front. In the court the principal object was the large brazen altar, on which all burnt-offerings and the appointed parts of other sacrifices were burned. Between this and the sanctuary itself was placed the brazen laver for the ablutions of the priests. This court was entered not only by the priests and Levites, but by all Israelites—who must be ceremonially clean—who came to offer sacrifices. The entrance to this also was by a hanging of curtains gorgeously wrought in colors, supported on pillars, and was 20 cubits in width. The three entrances were thus in one line, all facing eastward. The dimensions of the court were 100 x 50 cubits; it was inclosed on all sides by pillars of brass 5 cubits high and 5 cubits apart, resting in sockets of brass; and on these were hung, by hooks of silver, curtains, one for each side, of "fine twined linen."

Revised by S. M. JACKSON.

Tabernacles, Feast of: the last of the three great annual festivals, at which all the males of Israel were required to present themselves at the sanctuary (Lev. xxiii. 33-43). It began on the 15th Tisri, the first month of the civil and

seventh month of the ecclesiastical year, corresponding to the last part of September or first part of October, and continued seven days, with a supplementary eighth day. On the first and on the eighth day there were "holy convocations," when no servile work might be done, although the other activities of life were allowable. On the remaining days there was no legal restriction on labor, but from the manner of keeping the feast it must have been largely suspended. It was also called the "feast of ingathering" (Exod. xxiii. 16), and was pre-eminently a thanksgiving festival after harvest, and was far more joyously kept than any of the other feasts. It was distinguished by two peculiar observances—(1) the dwelling in booths, in memory of their wilderness wanderings. These booths were to be constructed of the branches of "goodly trees," and were not tents. According to Jewish tradition, the sides were built up of boards, and only the roof made of branches. The booths were placed on the roofs and in the courts of the houses, and in any unoccupied places in the streets. As little furniture as possible was to be placed in them, and it was not required that women and children should dwell in them, but only men. Tradition interpreted the word dwell to mean taking at least two meals a day in them. (2) The singular manner in which the sacrifices were arranged (Num. xxix. 13–38). There was offered daily a kid for a sin-offering, with two rams and fourteen lambs for a burnt-offering; but besides this there was a further burnt-offering of bullocks, thirteen on the first day, twelve on the second, and so on diminishing by one on each successive day, until only seven were offered on the seventh day. On the eighth day the sacrifices were a goat for a sin-offering, one bullock, one ram, and seven lambs for a burnt-offering. The Law required that at the feast of tabernacles in the sabbatical year the Law should be publicly read to the whole people, men, women, and children.

Two other customs arose at an early date: (1) One of the priests drew water in a golden pitcher from the Pool of Siloam, and brought it through the water-gate of the temple to the altar. As he entered, the trumpets sounded. Then, just before the offering of the sacrifices, the water was poured upon the altar, amid the joyous chanting of Ps. cxviii. on the part of the great concourse of people, in holiday attire and carrying *lulabs* or green branches tied together. So great was the joyousness of the occasion that it became a rabbinical proverb, "He has never seen joy who has not seen the joy of the pouring out of the water of Siloam." To this custom allusion is made in John vii. 37, 38. In the evening of the day of "holy convocation" the men and women assembled in the courts of the temple expressly to rejoice over the drawing of the water of Siloam in the morning, and gave themselves up to unrestrained hilarity. (2) On this occasion two great lights were set up in the court, each consisting of four lamps, the oil for which was supplied by the sons of the priests, and the wicks made of cast-off priestly garments. The light is said to have reached over nearly the whole city. The passage John viii. 12 is supposed to allude to this light. Revised by S. M. JACKSON.

Tabernæmontana: See COW-TREES and FORBIDDEN FRUIT.

T'bes Dorsalis, or Locomotor Ataxia [*tabes dorsalis* is Lat., liter., a wasting away (*tabes*) in the back; *locomotor ataxia* is in-coördination of movements; Mod. Lat. *locomotor* (Lat. *locus*, place + *motor*, a mover) + Gr. *ataxia*, disorder (*â-*, not + *adjec.* *taktós*, deriv. of *τάσσειν*, arrange)]: a chronic affection of the posterior columns of the spinal cord, characterized by in-coördination, sensory and nutritive disturbances, and a loss of the light reflex of the pupil. It is a disease of middle life, and is much more frequent in men than women. While syphilis is the most frequent cause, sexual excess, overwork with exposure, and possibly even injury may produce it. Alcoholism alone exerts but little causative influence. The disease usually begins with attacks of violent, stabbing pains in the legs, coming on suddenly and lasting only for a moment, recurring for months before the onset of other symptoms, and usually diagnosed as rheumatic. On examination the knee jerks are found to be absent, and later the superficial reflexes also disappear. The pupils are small, and while still contracting on accommodation cease to do so when exposed to light. This condition is called the Argyle-Robertson pupil. Optic atrophy may be present. Later the characteristic gait due to in-coördination appears. The foot is raised too high, is thrown violently forward, and the entire sole touches the floor at once.

Walking is made much more difficult by closure of the eyes, and on attempting to stand with the feet close together and the eyes shut the whole body sways sometimes so violently as to throw the patient to the floor (Romberg's symptom). The gait greatly resembles that of a drunken man. In-coördination is also present in the hands. On trying to touch the nose or ear with the finger, the eyes being closed, it goes wide of the mark. It is difficult for the patient to button or unbutton his clothes, and to pick up small objects without the aid of vision. There is no true palsy, but simply this inability to direct muscular effort, until late in the disease. Sensation is delayed, sometimes ten seconds elapsing between a touch and its recognition. The ability to localize sensation may be lost. There are spots of anæsthesia. The patient often feels as if walking on wool. Numbness and tingling occur in the hands and feet. Often a tight band is felt around the body. Attacks of violent pain in the stomach, with vomiting (gastric crises), are frequent. Laryngeal crises are characterized by noisy inspiration, dyspnoea, and cough. Infrequently there are crises in other organs. There is apt to be difficulty in micturition. Sexual power is entirely lost. Trophic changes occur. The most frequent are perforating ulcer of the foot, skin eruptions, changes in the larger joints characterized by erosion of the cartilages and effusion into the joint cavity, and brittleness of the bones rendering them peculiarly liable to fracture. The disease extends over many years. Death usually results from some intercurrent affection. While locomotor ataxia never causes disease of the mind, one form of insanity (general paralysis) occasionally begins with identical spinal symptoms. Fully developed locomotor ataxia is incurable, but treatment may benefit and for a time even stay the progress of its course. Pathologically *tabes dorsalis* is a sclerosis of the posterior columns of the spinal cord, with involvement of the posterior nerve-roots, the meninges, and sometimes a peripheral neuritis. WILLIAM PEPPER and C. W. BURE.

Table-land: See PLATEAU.

Tables: See FURNITURE.

Taboo', or **Tabu** [from Polynesian (Marquesas island), *tapu*, forbidden, (as noun) *taboo*]: a Polynesian interdict which makes persons, places, or things sacred, so that certain persons can not touch or come near them without becoming defiled and outlawed. The system of taboo penetrates the whole social life of most of the unchristianized Polynesian islands, and is a powerful agent in the hands of chiefs and priests in controlling the people.

Tabor, Mount [*Tabor* is from Heb. *Tābōr*, liter., lofty place (or perhaps stone quarry)]: an insulated mountain of Northern Palestine, in Galilee, 6 miles S. E. of Nazareth, rising 1,053 feet above the plain and 2,018 feet above the sea, and commanding a large and beautiful view of the surrounding country. It is often mentioned in the Old Testament, and was from the fourth century generally regarded as the scene of the transfiguration of Christ, although it is now known that at the time when that event took place its summit was occupied by a fortified town.

Revised by M. W. HARRINGTON.

Tabor College: a coeducational institution at Tabor, Fremont co., Ia.; incorporated under the name of Tabor Literary Institute in 1854 and reincorporated under the name of Tabor College in July, 1866. It is an outgrowth of a colony of Congregationalists from Oberlin, O., who formed the settlement at Tabor in 1852. Many citizens of Tabor gave largely of their property to the institution at the opening of the college department. The first nineteen donors gave in cash and notes 60 per cent. of the assessed value of their property. An academy was opened in 1857, and a college department in 1866. Tabor College includes classical, scientific, and literary courses of study of four years each, also a preparatory academy, an English course of four years, a conservatory of music, and a department of fine arts. The entire number of students in 1894 was 218. Rev. William M. Brooks, D. D., the present incumbent (1895), was principal of the academy and first president of the college. Tabor College has five buildings, 13 acres of land, a library of over 6,000 volumes, and a cabinet of 12,000 specimens. The property is valued at \$160,000. The number of students from the first exceeds 3,000. The faculty consists of eight professors and five instructors, besides a number of assistants. WILLIAM M. BROOKS.

T'aborites [from *Tabor*, one of their strongholds, 65 miles S. of Prague]: the radical wing of the Hussites (q. v.) or-

vanished in 1420 under Zikān. They opposed the Christians or Muzaffarids no less than the Rumis, and waged long defensive wars. They finally took the name of Ilkhanate (see p. 874).

Tabriz, or **Tabreez**, old name of the province of Azerbaijan, Persia; 30 miles E. of Lake Urmia (see map of Persia and Arabia, vol. 1-4). It is in the midst of a fertile and well-cultivated plain, where there are many orchards and vineyards. The city itself is surrounded by gardens that are irrigated by the adjacent streams. It is purely built, with crooked, narrow, and dirty streets and no important public edifices, except the remains of the Blue Mosque, a model of Eastern architecture and decorative art that was destroyed by the earthquake of 1780, and the ark minaret, containing the pulpit of the last-imam. Its houses are more buildings, but extensive, and there are important manufactures of silk, wool, shawl, tobacco, and leather, and a large transit trade. Though a Persian tradition tells us that Tabriz was built by Zohabā, the wife of Haydar-al-Bakhti, the town was known in antiquity under the name of *Gasteron*, and was the capital of the Median province, *Atropatene*. Marco Polo visited it about 1263. It has suffered severely by fire, earthquake, and by the invasions of Turks. Pop. estimated at 160,000.

Revised by M. W. HARRINGTON

Tabu: See **TABOO**.

Tabulae: a name formerly given certain corals, both young and fossil, from the fact that the pits (calices) in which the animals lived are divided by transverse partitions or *tabulae*. The group is an unnatural one, some of the forms belonging to the *Hydraea*, the others to the *Scyphozoa*.

Tab'ahool, or **Bahn**: a nutpall which grows on a lamellar (*Thamnia indica*). It is valuable as a prolific source of gallic acid. Large quantities are exported from India and Barbary.

Tab'amahoe: the resin of various trees (1) of *Myrica salicifolia*, a tree of Guayana and Venezuela; (2) of the limbs of the balsam-poplar, which grows in the U. S. (*Populus balsamifera*); (3) of *Calophyllum rotundifolium*, *C. laevis*, and *C. lucidum*, Old World tropical trees, producing East Indian lacumahoe; (4) the Mexican *Quercus* (q. v.). These articles are sometimes used in medicine; all but the second are employed in varnishes, incense, etc.

Revised by CHARLES E. HENRY.

Taché, ta'h'sha, Sir EUGENE PACHAÏ; statesman; b. at St. Thomas, Quebec, Canada, Sept. 5, 1795; d. there July 29, 1865. He served in the war of 1812; studied medicine and practiced as a physician till 1841, when he entered Parliament; was commissioner of public works 1848-49; Speaker of the Legislative Council 1850-57, and was knighted in 1855. He wrote *De développement de la force physique chez l'homme* (Montreal, 1829) and *Recherches sur l'organisation des colonies* (Quebec, 1833).—His son, JOSEPH CASHEL, author, b. at Kamouraska, Quebec, Dec. 24, 1826, graduated as a physician in 1844; was a member of the Legislative Council 1847-57; represented Canada at the Paris Exposition in 1855; at that in London in 1862, and was British delegate from Canada at the international sanitary conference at Washington in 1881. He wrote *Esquisse sur le Canada* (Paris, 1855); *Yamers mémoires en Canada* (Quebec, 1854); *Les pèlerins rouges* (1854); *Trois légendes de mon pays: Forestiers et voyageurs*, and other works.—Another son, ALEXANDRE ACHIN, Roman Catholic archbishop, b. at Rivière-du-Pas, Quebec, July 23, 1823, graduated at the College of St. Hyacinthe; studied theology at the Seminary of Montreal, and became a monk of the Oblate order. He served as a missionary among the Indians of the Red River country; was ordained a priest in 1845; consecrated bishop of Arch. in *partibus* in 1859; Bishop of St. Boniface in 1860, and in 1871, when St. Boniface was erected into a metropolitan see, Bishop Taché was appointed the first archbishop. While attending the council of the Vatican at Rome in 1869, the Canadian Government begged him to return and use his influence with the Mills of Manitoba, who were in a state of insurrection. He returned at once, and empowered by the British and Dominion Governments to offer full pardon in the rebellious Mills, helped successfully to restore peace and allay disaffection. D. at Winnipeg, Manitoba, June 22, 1894. He was the author of *Vingt années de missions dans le nord-ouest de l'Amérique* (Montreal, 1869); *Népalais sur le nord-ouest de l'Amérique* (1869), and other works.

NEIL MACDONALD.

Tachyura: See **BEAUTY DUCK**.

Tachyglossidae (Mod. Lat., named from *Tachyglossus*, the typical genus; Gr. *tachys*, swift + *glossis*, tongue); a family of Australian mammals, of the order *Monotremata*, represented by the so-called hedgehogs, which most and are confounded with the hedgehogs of Europe. *Tachyura*, a name often used, is preoccupied in zoology. The face and jaws are produced into a long and tubular snout, at the end of which is the small mouth; teeth are entirely wanting, but on the palate are robust bony spines, pointing backward; the tongue is subcylindrical, and very long, flexible, and protrusible, and armed with numerous barbed spines; the surface of the body and head above and on the sides is armed with long, stout, tapering, and pointed spines, intermingled with coarse hair, and below is clothed chiefly with simple coarse hair; the limbs are short and robust, each provided with five toes; the males are provided with bony spurs to the hind feet; the tail is rudimentary. The *Tachyglossus* attains a length of about 15 inches, but the *Zaglossus* of New Guinea is much larger. They feed chiefly on ants and other small insects, as is indicated by the small mouth and extensible tongue, but sometimes take in grass. The ants are chiefly sought for by digging, for which the animals are eminently adapted. "In soft alluvial soil or sand an echidna will disappear before the observer's eyes, apparently without any effort, gradually sinking out of sight." (See p. 879.) Like their relatives, the duckbills, they develop one of large skin, compared with those of other mammals; but, instead of "laying" two, as the duckbill does, the female matures a single one, which is covered about in a pouch formed by a fold of the skin, somewhat like the pouch, or "marsupium," of an opossum and other marsupials. As in the species, differences of opinion prevail. Until recently only one was generally recognized. There are two very distinct genera, (1) *Tachyglossus* or *Echidna*, and (2) *Zaglossus*, *Acrotylommus*, or *Proechidna*. Of the former, three closely related modifications (species or subspecies) exist—one in Australia, one in Tasmania, and one in New Guinea, known respectively as *E. setacea*, *E. setosa*, and *E. tasmani*; and of the latter, two in New Guinea, *P. browni* and *P. nigrescens*. Revised by F. A. LUCAS.

Tachygraphy: See **STENOGRAPHY**.

Tachypetidae (Mod. Lat., named from *Tachypetes*, the typical genus; Gr. *tachys*, swift + *petes*, fly); a family of birds represented by the frigate bird or man-of-war of mariners. The form is somewhat the same as that of pelicans, but the neck is shorter, and the anterior position of the legs imparts to the bird a peculiar appearance; the bill is longer than the head, rather slender, and contracted toward the middle, and nearly straight, but with the end strongly hooked; the sheath is composite or grooved, as in all the *Phalacrocoracidae*, the edges are entire, the wings are very long and pointed; the tail is also very long, is very deeply forked, and has twelve feathers; the legs are inserted unusually far forward, and are small; the tarsus being, proportionally, the smallest in the entire class of birds; the toes are slender, and the web between them deeply indented. The sternum is small and short, the coracoids long, the furcula ankylosed with the sternum and coracoid. The family belongs to the same group (*Steganopoda*) with the *Phalacrocoracidae* (frigatebirds), *Fulidae* (cormorants), *Phalacrocoracidae* (cormorants), *Alcedinidae* (kingfishers), and *Coliidae* (goatsuckers). As to habits of species, see FRIGATE BIRD. Revised by F. A. LUCAS.

Tacitus, MARCUS ULPIUS; Roman emperor 275-276; b. at Interamna (Terra), in Umbria, about 90 A. D.; was noted as one of the oldest senators and one of the wealthiest citizens when the senate, on the death of Aurelian, elected him emperor. He was a man of upright and pure character and of literary tastes, claiming descent from the distinguished historian whose name he bore. It was his ambition to reanimate the senate in its former authority, improve the morals of the people, and check the confusion in public affairs. He waged a successful war with the Alani, but died soon afterward at Tarsus or Lyons, in Asia Minor. According to some authorities he was murdered by his soldiers.

F. M. COLBY.

Tacitus, PRAESES CASSIUS; author; b. about 54 A. D. His birthplace is not known; in some MSS. and by Aquinas Apollinaris he is called Galus; but the phenomenon Tacitus is established by a Greek inscription found at Myra, first published in 1890, which also proves that late in life he was president of Asia. He married a daughter of C. Julius

Agricola in 77 A. D.: was prætor in 88; consul suffectus in 98, and probably survived Trajan, who died in 117. He had already acquired great reputation as an orator when Pliny entered public life. They became intimate friends. Of Pliny's letters, eleven are addressed to him, and it is apparent that his friendship was considered by Pliny as a distinction. As an author he was much appreciated by his contemporaries, as well as by the writers of the following century. The Emperor Tacitus claimed relationship to him, and ordered his works to be placed in all public libraries, and ten copies to be made every year at the public expense and deposited in the archives. During the latter part of the Roman epoch and during the Middle Ages he was not much read, and most of his works have been handed down only in a mutilated and corrupted form. The dialogue *De Oratoribus* is his earliest work; its authenticity has been denied by some scholars, but is generally accepted. The *Agricola*, a biography of his father-in-law, is an artistic masterpiece, and of special interest on account of the fact that Agricola spent so much of his time in Britain. The *Germania* or *De Situ ac populis Germaniæ* is an ethnographical-geographical work, of the greatest value for its description of early Germany. Some scholars look upon it as a political pamphlet or as serving a moral purpose. Of his *Historiæ*, written before the *Annales*, only the first four and a half books are extant, giving the history of the years 69-70 A. D. Of the *Annales*, beginning at the death of Augustus—hence the proper title *ab excessu divi Augusti*—and ending at the death of Nero, 14-68 A. D., only the first four books, part of the fifth, the sixth, and from the middle of the eleventh to the middle of the sixteenth, are extant. The style of these writings is very peculiar. To the common reader it is harsh and obscure, yet at the same time exceedingly powerful. Scholars who are familiar with the author generally admire not only the intellectual and moral, but also the literary character which these works show. Editions by Bekker (Leipzig, (1831), Orelli (Zurich, 1846 and 1848, and revised by other scholars 1850, and Berlin, 1877), Ritter (1848), and Halm (1884). Of the *Annales*, Nipperdey-Andresen (Berlin, 1892); *Germania*, Zernial (Berlin, 1890); *Agricola* and *Germania*, Hopkins (Boston, 1893); *Dialogus*, Andresen (Leipzig, 1891); A. Gudeman (Boston, 1894); *Historiæ*, Spooner (London, 1891); *Annales*, Furneaux (vol. i., 1884; vol. ii., 1892, Oxford). English translations by Gordon (1728-31), by Murphy (1793), and by Church and Brodribb (London, 1876-77). Revised by M. WARREN.

Tacking: a doctrine of English equity whereby a subsequent mortgagee or incumbrancer for value is allowed on discovering the existence of intervening incumbrances, of which he was ignorant when he advanced his money, to purchase the first mortgage and compel the intervening incumbrancers to pay off not only the first mortgage, but also his own incumbrance under penalty of losing the property by a foreclosure. This inequitable doctrine of English equity, by which a subsequent incumbrancer is enabled to "squeeze out" intervening incumbrancers, is an unjustifiable exception to the rule that as between conflicting but equal equities that which is prior in point of time prevails, and has found no acceptance in the U. S. WILLIAM A. KEENER.

Tacking and Wearing: the common methods of working a vessel from one tack to the other; they differ in that while in tacking the vessel turns toward, in wearing it turns from the wind. Square-rigged vessels when close-hauled lie within about six points of the wind; fore-and-aft rigged vessels lie a point or two higher; therefore, in tacking a ship turns through twelve and in wearing through twenty points of the compass. A vessel wears when, through high winds or heavy weather, or some other reason, tacking is impracticable. If in tacking a vessel comes up into the wind and lies there, it is said to be *in irons*; it may then by shifting the helm be made to fall off on the other tack when stern-board is gathered, otherwise it may be boxed off on the same tack. See BOX-HAULING. CHARLES BELKNAP.

Tac'na: the northernmost province (provisionally) of Chili, bordering on Peru, Bolivia, the Chilean province of Tarapacá, and the Pacific. Area, 8,686 sq. miles. The Andes on the E. separate it from Bolivia, and there is a coast range rising in parts to 3,000 feet. Most of the intermediate space is a rainless desert; but this is crossed by the valleys of several streams, and wherever they afford sufficient moisture the land is well fitted for cultivation. The streams are scanty and intermittent, and there is no good system of irrigation. Some of the valleys are insalu-

brious, and the climate everywhere is hot; earthquakes are frequent. Silver, copper, etc., occur, but are mined only on a small scale. A portion of the commerce of Bolivia passes through Tacna, but railways are rapidly drawing it into other channels. The scanty population (29,523 in 1885) is nearly all gathered at Tacna, the port of Arica, and two or three other points. Tacna is divided into the departments of Tacna and Arica. Formerly these were provinces of the Peruvian department of Moquegua. They were occupied by the Chilians, after several battles, in 1880. By one of the clauses of the treaty of peace between Chili and Peru, ratified Mar. 31, 1884, it was agreed that the former republic should hold Tacna and Arica for ten years; at the end of that time the people of the territory so held to decide, by a popular vote, which country they will belong to: the country so chosen to pay \$10,000,000 to the other. This decision should have been made in Mar., 1894. Owing to the disturbed state of Peru, and to financial difficulties in both republics the question has been postponed, and is still (1895) unsettled. HERBERT H. SMITH.

Tacna: capital of the province of Tacna, Chili: in a fertile valley near the western base of the Andes; 48 miles by railway from its port, Arica (see map of South America, 6-C). The plain is irrigated from the little river Tacna. The town is well built, has a seminary, hospital, and small theater, and a fine public promenade. The water-supply is scanty and bad. Tacna has many foreign merchants, who control the trade with Bolivia across the Andes. Formerly this was very important, and it is still considerable. During the first year of the war of the Pacific (1879), Tacna was the principal post of the allied armies of Peru and Bolivia. Here, on May 27, 1880, they were defeated by the Chilians, under Gen. Baquedano, abandoning the town and, soon after, the province. Pop. about 15,000. H. H. S.

Taco'ma [from the Indian name for Mt. Tacoma or Mt. Rainier]: city; seaport; capital of Pierce co., Wash.; on Commencement Bay, the Puyallup river, and the N. Pac. and the Tac., Lake Park and Columbia Riv. railways; 25 miles N. E. of Olympia, and 41 miles S. of Seattle (for location, see map of Washington, ref. 4-D). It is on the western shore of Commencement Bay, on the east side and near the southern extremity of Puget Sound. The Puyallup river empties into the bay within the city limits, and aids in making a fine natural harbor, and the shipping facilities and regulations are excellent.

Plan and General Appearance.—Most of the manufacturing and railway industries are in the eastern part, on or about the level tide-flats at the head of the bay. The business and residence portions are on a bluff 80 feet above the water, on ground rising gradually to 320 feet, to a level plateau, over which the city is spreading. The principal streets are 100 feet wide, and the others 80 feet. The surrounding waters, forests, and snow-capped mountains are of unusual grandeur, with the Olympic or Coast Range in the west and the Cascade Range in the east; Mt. Tacoma (by some called Mt. Rainier) rises to a height of over 14,400 feet. Wright Park, containing 40 acres, and Point Defiance Park, 662 acres, are the principal parks. The region immediately S. of the city, interspersed with numerous lakes, is a park land of much beauty. The city owns the water and electric-light plants, on which have been expended about \$2,000,000; cable and electric street-car lines reach all sections of the city and several suburban resorts and other towns. There are about 120 miles of graded streets, and 60 miles of sewers. Notable buildings include the county court-house, city-hall, Tacoma hotel, the offices of the Northern Pacific Railroad, Tacoma theater, Union Club, Chamber of Commerce, and a number of modern office buildings.

Churches, Schools, and Charities.—The church organizations are divided denominationally as follows: 15 Methodist Episcopal, 8 Presbyterian, 8 Lutheran, 7 Protestant Episcopal, 6 Congregational, 6 Baptist, 5 Roman Catholic, 2 Christian, 2 Christian Science, 2 Salvation Army, and 1 each Adventist, German Evangelical, United Presbyterian, Scandinavian Free Evangelical, Spiritualist, Jewish, and Universalist, besides the First Free Church of Universal Religion. The aggregate membership of the churches is about 10,000. The public schools embrace a high school, with a manual-training department, and grammar and primary schools, occupying twenty buildings (cost, with their sites, nearly \$1,000,000); daily attendance of pupils, about 5,000; teachers employed, 125; annual cost of maintenance, over \$200,000. There are 16 private schools, academies, and

highways, colleges, the most prominent institutions being the Union Wesleyan Seminary (Kitsap) for girls, the Pacific University (Guthrie), the Puget Sound University (Methu), Washelli College (near Seattle), and the Roman Catholic parochial schools. The city and other public libraries, the Ferry Museum of Art, and kindred organizations add to the educational advantages. The charitable organizations and institutions are the Associated Charities, City and County Hospital, Fanny Paddock Memorial Hospital, St. Joseph's Hospital, Grand Army Relief, Children's Home, Seamen's Friend Society, and numerous charities connected with the churches and social societies. The Washington State Asylum for the Insane is 8 miles S.

Finance and Banking.—The assessed valuation in 1904 was \$30,453,813, and the bonded indebtedness Jan. 1, 1905, \$3,740,000. There are 14 banks—4 national, 5 State (including 4 savings-banks), and 2 branches of foreign (London) banks. A clearing-house was organized in 1890.

Business Interests.—In 1881 a cargo of wheat valued at \$91,000 was shipped from Tacoma to Liverpool, in an American bottom. Since then there has grown an ocean commerce which in 1894 aggregated \$8,000,000 in exports to foreign countries, composed of wheat, flour, coal, lumber, canned salmon, and miscellaneous merchandise; and the imports—mostly from China and Japan—amounted to more than \$10,000,000. The coastwise shipping to and from this harbor is extensive. About \$5,000,000 is invested in manufacturing industries. The plants include saw-alops (cost \$1,500,000), in which about 300 men are regularly employed, and several sawmills with a capacity of 1,100,000 feet per day, employing about 200 men. Over 3,000 persons are employed in other works, such as box-factories, breweries, rolling-mills, foundries, machine-shops, shipyards, smelters, packing-houses, match-factories, furniture-factories, planing-mills, truckyards, wheat elevators, warehouses, flour-mills, and shingle-factories. The value of the wholesale and jobbing trade is about \$15,000,000 per annum. The lumber and shingle trade of the city extends as far E. by rail as New York, no less than 125,000,000 shingles and 16,526,000 feet of lumber having been shipped eastward during 1894. Having a transpacific steamship line to the Orient, stopping at Yokohama and Hongkong, a clipper-ship line to South Africa, steamship connection with Alaska and Pacific coast ports, and railway connections with all parts of the U. S., Tacoma is one of the most important shipping and distributing points on the Pacific coast.

History.—Tacoma City, now the first ward and popularly called Old Town, was laid out in 1868 by Gen. M. M. McCarter. On July 14, 1871, the Northern Pacific Railroad Company established its Pacific terminus on Commencement Bay, naming it New Tacoma; in 1880 the town became the county-seat; and in 1883 the two towns were consolidated as Tacoma. Pop. (1890) 720; (1890) 36,000; (1895) estimated, 50,000. WALTER J. THOMPSON.

Tacoma, Mount. See RAISER, MOUNT.

Taconic, or Targhanic: a range of mountains extending nearly N. and S. along the eastern boundary of New York, and uniting the Green Mountains of Western Massachusetts with the Highlands of the Hudson. Its highest peaks are Equinox Mountain in Vermont, 3,947 feet, and Greylock in Massachusetts, 3,905 feet.

Taconic System: in geology, a group of strata in Western Massachusetts and Vermont and Eastern New York, representing the Cambrian period. The system was named by Prof. Elmore Easton in 1842, and further described and defined in subsequent papers. It was asserted by some of his contemporaries that these rocks are not pre-Potsdam, as claimed by him, but are the metamorphosed equivalents of formations of the New York system. The discussion of this question, known as the Taconic controversy, was animated and bitter, and its literature is voluminous. In later years it has been claimed by some geologists that Taconic should be substituted for Cambrian as the name of the first Paleozoic period, and this contention has been warmly sustained, though having little influence on usage. The question turns partly on the facts of history, and partly on the extent to which and manner in which the law of priority should be applied to questions of stratigraphic nomenclature. See CAMBRIAN PERIOD and GEOLGY, and consult E. Easton, *Geology of New York*, part II. (1842); *The Taconic System* (1844); *American Geology* (1855); J. D. Dana, *A Brief History of Taconic Ideas* (*Am. Jour. Sci.*, 3d series, vol. XXV, 1890); *List of Papers on the Taconic System* 1897.

Winchell, *Some Objections to the Term Taconic—Considered* (*Am. Geol.*, vol. I, 1886); C. H. Watkins, *Thematic System of Taconic* (*Am. Jour. Sci.*, 3d series, vol. XXV, 1890). H. K. GRANGER.

Tactics (plur. of *tactic*, from the *tactikos*, pertaining to arrangement, especially to military arrangement, deriv. of *tactos*, drawn up, deriv. of *taxis*, arrange, draw up (troops, Cf. Gr. *taxis* (the system, art), and *ta* (arrange, tactic)). The art of drawing up military or naval forces in order of battle and of performing military or naval evolutions. It may be treated successively under two heads:

Military Tactics.—This is the art of so handling bodies of troops, large or small, as to utilize to the fullest extent the fighting, maneuvering, and resisting capacity of every individual weapon, and resources of all arms of the service. When applied to the combined action of larger masses made up of different arms, on the field of battle, it is called grand tactics. When restricted to actions of small bodies or single arms it is called minor tactics. The two divisions run inseparably into each other.

Minor tactics include as one of their branches drill-regulations, or drill, formerly called in the U. S. by the general name of tactics. The object of drill is (1) to enable the commanding officer to place each and every soldier in the spot he is to occupy, in any desired formation, in the most rapid manner consistent with complete control of the man at all stages of the movement; (2) to enable the soldier to use his weapon in the most effective way in action, and to carry it with the least fatigue when marching; (3) to execute properly formations and movements of ceremony, such as parades, reviews, etc., which are necessary to preserve the pride of the soldier in his own appearance and that of his command. The accomplishment of these objects requires that drill-regulations should be devised with a view to simplicity and ease in learning, and fitness for handling troops, not only with full ranks, but also when their smallest subdivisions have been cut up and made of different sizes by the casualties of action. The field of minor tactics has been so extended as to embrace the subjects of information and security, including outposts, reconnaissance, and the handling of advance and rear guards; marches, instruction of the three arms in all that refers to the use of their weapons, and their employment upon the field of battle. In the latter respect sometimes it encroaches upon that of grand tactics.

The minor tactics of the different arms must conform to the changes and improvements in weapons. These require corresponding changes in formations, etc. The prime factor in these changes has been the weapon of the infantry; the vast improvements which have been made in cannon have also had their effect, but since these improvements are more in greater measure at the longer ranges than in destructiveness at close quarters, their influence upon tactical measures has been of the same kind and concurrent with that produced by the increased range of the infantry weapon.

The most marked change which results from the increased range and accuracy are forcing the enemy to deploy and open fire at much greater distance than formerly, enlarging very much the area covered by the effective fire of a battery, thus necessitating fewer changes in its position and giving a larger latitude in its selection. They also allow the artillery to open the combat at a distance from the enemy which can be traversed by him only with such losses and in such time that the artillery may safely march at the head of a column, open fire, and receive support before it is endangered by the approach of the enemy, and this advantage is gained without the loss of its effective fire at short range, which it may use in assisting the infantry in close action as formerly.

The correct tactical use of artillery requires the concentration of its fire upon properly selected targets, and the modern improvements have added largely to its efficiency by facilitating this; while the great distance at which a destructive fire can be poured upon a body of cavalry, by both artillery and infantry, has almost entirely changed the tactical use of mounted troops on the field of battle, narrowly limiting the opportunities for a successful charge upon infantry or artillery in position.

The changes made since the time of the Romans in the arms and equipments of the cavalryman, as distinguished from the dragoon or mounted infantryman, have reduced

themselves almost entirely to the addition of the revolver and the abolition of body-armor. The first adds somewhat to his aggressive value, while the second is the direct result of the improvement in the infantry weapon. This alteration in equipment has, however, introduced no material change in the tactics of combat of bodies of men fighting mounted, the detailed regulations and instructions for which in the most modern treatises correspond in every respect with the methods used by the cavalry of the Romans. The most marked change in the organization and the tactics of modern cavalry is the conversion of all mounted troops into dragoons, armed with a rifle or carbine, and trained to fight on foot or mounted as necessity determines; or even in some cases into mounted infantry who use their horses for transportation only and fight altogether on foot. In recent operations cavalry has been used as a veil or screen, to cover the advance of the rest of the army, to a much greater extent than it was formerly, although cavalry has frequently been used in this way in times past; a notable instance being Napoleon's use of Murat in his advance upon Ulm in 1805. Scouting, reconnaissances, and map-making have become a most important part of the duties of cavalry, and instruction in the methods used in the field form an important part of the tactical instruction of the trooper and his officers.

The modern minor tactics of infantry, in order to fulfill the requirements laid down in the definition above given, are designed with a view to beginning an action with a dispersed skirmishing line, in which the front of each battalion or company is covered by its own men, who are re-enforced and strengthened by their own comrades and commanded by their own officers, thus avoiding the disorganization resulting from mingling different commands on the front line of battle. In attempting to accomplish this, great prominence is necessarily given to the advance of successive lines in open order, which, by short rushes and by taking advantage of all possible cover, may diminish as much as possible the losses caused by modern small-arms and machine-guns, and at the same time collect for the final charge a strong line of companies and battalions. It is not to be expected that any single method will be approved by all military men, but each of the great nations has a system which, under the constant supervision and study of its officers, is modified as new developments are made in weapons and new lessons learned from experience in war.

Grand tactics includes planning battles, perfecting the preliminary arrangements, conducting them during their progress, and securing the results of victory or avoiding the consequences of defeat. It is concerned generally with the action of the several arms in combination on or in the immediate vicinity of the battle-field; but it reaches out on the one hand into the domain of logistics and strategy in the movement of troops and the character of battle sought, and on the other into that of minor tactics in the handling and placing of the different arms upon the field. It is essentially the province of generals, and one in which they should have full and unrestricted command, as success or failure almost invariably results from the character of the position selected, the manner in which the troops are placed, and the instant at which the different bodies are brought into action. These questions can be decided only by the commander present on the field and as they arise.

Battles are usually preceded and followed by minor actions, classed as combats, skirmishes, etc., which are generally not intended to be decisive, but arise between detached parts of the main army, and which may cease without marked effect or may be continued and finally merge into the general battle. Battles are classed as offensive, defensive, and defensive-offensive, the latter name being applied to those actions in which the attack having exhausted its strength, the defense takes the offensive to gain the victory. In great battles the fighting is not carried on in the same manner at all points of the line. False attacks and demonstrations of the class known as "containing movements" are made at some parts of the line, while the strength of the attack is concentrated at another, thus "making one's self stronger than the enemy at the time and place of actual conflict," which is the guiding principle in all the operations of the art of war, and is the very soul of success in battles.

It is this principle which, by overshadowing all others, has led to the statement that "the rules of tactics are invariable and are the same now as they were in the time of Alexander." This is true only of grand tactics.

In open battle it is evident that the application of the

above-given principle is most easily made by the offensive, which also generally develops the enthusiasm of the men and, in case of success, will usually render the result decisive. History shows that success has generally attended the aggressive leader when other things were equal; but when an army is weak in men, in training, or in morale, its leader can only seek to give it superior strength in actual conflict by fighting a defensive battle in a well-selected position made strong by fortifications, against which the enemy may exhaust his superior strength.

Much has been written, with very little profit, upon the orders of battle, with their relative advantages. These so-called orders result, as a rule, from the natural features of the ground in the first position and from the development of the strong attack when the battle opens. Necessarily, if the lines remain in contact when one assumes a "convex order," the other must take up a "concave order," and *vice versa*; while the great and manifest advantages which result from an oblique attack upon one wing, by which it is rolled back and beaten in detail, are obtained either by overlapping it or by throwing against it a preponderating force. Any attempt to take up a geometrical "oblique order" would, as a rule, be at once seen by the enemy, who would take measures to meet it. The same is true of the other orders. The use of the terms, however, when properly understood, may be convenient in the description of battles, if too much weight be not given to them.

The works upon tactics are very numerous; see especially Home's *Précis of Modern Tactics* (London, 1878); Boguslawski, *Tactical Deductions from the War of 1870-71* (London, 1872); Clery, *Minor Tactics* (London, 1883); Shaw, *Modern Tactics* (London, 1884); Mayne, *Fire Tactics* (London, 1888); Meckel, *Éléments de la Tactique* (Paris, 1887); Clausewitz, *On War* (London, 1873); Jomini, *Art of War* (Philadelphia, 1877); Mercur, *Elements of the Art of War* (New York, 1894); Derrecagaix, *Modern War* (Washington, 1888). See also FORTIFICATION, STRATEGY, and WAR.

JAMES MERCUR.

NAVAL TACTICS.—The subject may be divided into grand tactics, or the tactics of battles, and elementary tactics, or the tactics of instruction. The history of naval tactics can very properly be separated into three grand divisions. The first, which may be called the oar period, begins where tradition merges into authentic history, and ends about the time of the battle of Lepanto (1571), covering a period of about 2,000 years. The second, or sail period, may be said to be embraced between Lepanto and the battle of Lissa (1866), lasting only 295 years, since which time there has been only the steam period, which is yet in its infancy. The sail period having completely passed away, and the tactics under oars being based upon the same general principles as steam tactics, the latter alone will be described.

The key to any system of naval tactics is the line of battle. If, in the line of battle, the vessels are all in line—or, as it was called in the tactics under sail, "line abreast"—and heading toward the enemy—we have the line of battle of the oar period, when war-galleys were armed at the bow with a spur (rostrum), and depended for success in battle on ramming and sinking the galleys of the enemy or grappling and boarding him. This formation gives us also the line of battle of modern fighting ships when their principal offensive power lies in their rams. If, however, the power of the ship lies in her broadside (artillery placed on the side of the ship), it is obvious that such ship must present her broadside to the enemy, in which case the line of battle must be the "line ahead," or, as it is now properly called, in "column." In addition to the above, there are certain "orders" in which it is convenient for a fleet or squadron to navigate the sea, to go in and out of port, to anchor and to get under way. To change from one of these orders to another, or to change from any given order of steaming to the order of battle, constitutes elementary tactics. The disposition of the fleet for actual contact with the enemy under various conditions constitutes grand tactics. It was in the tactics of battle that Nelson's genius was most conspicuous. The following definitions have been adopted with a view to securing uniformity of movement in tactical evolutions: The coefficient of speed is the ratio between the number of revolutions per minute of the engines of a given ship and those of the flag-ship, when the speed of both is the same; the coefficients of helm are the ratios between the angles of a given ship's helm and those of the flag-ship's helm when describing the same circle.

Fleet Tactics under Steam.—An assembly of twelve or more

line-of-battle ships, or vessels of equal military value, is called a *fleet*, and is separated into three divisions of one,

FIG. 1.

two, or three squadrons each, each squadron comprising not less than four vessels. The commander-in-chief commands

FIG. 2.

The line, the order of battle for line-of-battle ships, rams, and torpedo-vessels, is formed as in Fig. 1.

The column is the order of battle for vessels whose principal power is in their broadside batteries. (Fig. 2.)

FIG. 3.

Double echelon orders are offensive (salient angle) and defensive (re-entrant angle) for vessels for all descriptions. (Fig. 3.)

Vessels are said to be in direct single echelon when, steering the same course, each bears from its next astern at an angle of 45° (four points) from the course; consequently the wings of a fleet in double echelon form a right angle. One vessel should always be designated by signal to act as guide, by which the movements of the other vessels are to be governed, and should wear a guide-flag at the main. When maneuvering, the vessel upon which a formation is made

FIG. 4.

must necessarily be the guide. When the fleet is in line in natural order, the van squadron is on the right. (Fig. 4.) This was the line of battle formed by Callicratidas, the Spartan, at the battle of Arginusæ, his fleet being composed of 300 galleys. The fleet in column is in the natural order when the van squadron is leading.

Fig. 5 exhibits the fleet in column of squadrons, or of

FIG. 5.

the explorer of the Mississippi. It contains the oldest church edifice erected in Canada. From Tadousac to the Gulf the salmon and sea-trout fishing is unsurpassed. Pop. of district, 2,400. J. M. HARPER.

As the single column may be broken and the rear ships cut off, it, too, should be re-enforced as in Fig. 2. In any case, there should be a reserve (R, Fig. 2), ready to succor any portion of the fleet that may need it.

A strong order of battle is the French *peloton* formation, for facility of maneuvering, affording mutual support, etc.

FIG. 6.

Three vessels act as a unit, and these *pelotons* may be formed in line (Fig. 6), in column (Fig. 7), or in echelon.

The simple orders are the line, column, and echelon; compound orders are those wherein the squadrons or divisions, considered as units, are ranged on one of the simple orders. See *Naval Tactics* (New York, 1859), by J. H. Ward, U. S. navy; *Fleet Tactics under Steam* (1863), by Com. F. A. Parker, U. S. navy; *Naval Warfare with Steam* (1832), by Sir Howard Douglas; *Tactique Navale*, and *Fleet Drill-book*, U. S. navy.

Tacubaya, *tā-kōō-bā-yā*: a town of the Federal District, Mexico, 3 miles S. W. of Mexico city (see map of Mexico, ref. 7-G). It is a fashionable suburb of the capital, and is associated with many episodes of the later history of the republic. The castle, military school, and observatory of CHAPULTEPEC (q. v.) are included in it. Pop. (1889) estimated, 12,000. H. H. S.

Tacunga: See LATACUNGA.

Tadmor, or Thadmor: See PALMYRA.

Tadousac: a summer resort in the united Chicoutimi and Saguenay Counties, Quebec, Canada; near the confluence of the Saguenay with the St. Lawrence, on a semicircular raised beach of sand (see map of Quebec, etc., ref. 2-E). Tadousac is the oldest village in Canada, having been a center of the fur-trade in early days. The Jesuits had a religious establishment here, of which only the traces of the foundation remain, and for a time it was the home of Father Marquette, the explorer of the Mississippi. It contains the oldest church edifice erected in Canada. From Tadousac to the Gulf the salmon and sea-trout fishing is unsurpassed. Pop. of district, 2,400. J. M. HARPER.

Tadpole [Mod. Eng. *tadd-pol*; *tudde*, toad + *polle*, head, poll]: the larval or young stage of the frogs (*Ranidae*), which is distinguished by the large head, compressed tapering tail, and (in the youngest stage) want of legs. The name is also applied to the corresponding stage in other amphibians and even to the larvæ of many ascidians, having a superficial resemblance to the tadpoles of frogs. See BATRACHIA, FROG, and TUNICATA.

Tael, *tāl* [Portug., from Hindi *tola*, through Malay *tahil*, weight]: the name, in common use among foreigners in China and Hongkong, for the Chinese *liang* or ounce of fine silver, the monetary unit of reckoning there. It equals in weight 1½ oz. avoirdupois. The haikwan tael is the standard recognized by the customs authorities. See CHINA.

Tænia: See TAPEWORM.

Tænioglossa [from Gr. *ταῖνια*, ribbon + *γλῶσσα*, tongue]: a large group of molluscs. See MONOTOCARDIA.

Taft, ALPHONSO, LL. D.: jurist; b. at Townshend, Vt., Nov. 5, 1810; graduated at Yale 1833, where he was afterward tutor and law student; was admitted to the bar 1838, and moved to Cincinnati, O., in 1840; judge of superior court of Cincinnati 1865-71; resigned and resumed practice of law; U. S. Secretary of War Mar. 8 to May 22, 1876; Attorney-General U. S. 1876-77; appointed envoy extraordinary and minister plenipotentiary of U. S. to Austria Apr. 26, 1882, and to Russia in 1884; resigned in Aug., 1885. D. at San Diego, Cal., May 21, 1891.

Taganrog: town; in the government of Ekaterinoslav, Russia; on the N. shore of the Sea of Azov, opposite and 18 miles W. of the mouth of the Don (see map of Russia, ref. 10-E). It was founded by Peter the Great, and was a favorite residence of Alexander I., who died here Dec. 1, 1825. Though its harbor is so shallow that ships must load half a mile from the shore, it carries on a large export trade in timber, hemp, copper, tar, wheat, and meat. Pop. (1890) 48,999. E. A. G.

Taghkanic: See TACONIC.

Taglioni, *taäl-yo'née*: the name of a celebrated family of dancers and ballet-masters, of Italian origin, but principally connected with the royal theater of Berlin. The most illustrious member was MARIA TAGLIONI, b. in Stockholm, Apr. 23, 1804. She made her *début* in Vienna in 1822, danced subsequently in all the capitals of Europe, and created great enthusiasm, especially by her performance of the title-role in her father's ballet *La Sylphide*. She retired in 1847, and lived in Venice and at Lake Como. D. in Marseilles, Apr. 23, 1884.—Her brother, PAUL TAGLIONI, b. in Vienna, Jan. 12, 1808, was ballet-master in the royal theater of Berlin, and composed the ballets *Sardanapal*, *Satanella*, *Flick und Flock*, and others. D. in Berlin, Jan. 7, 1884.

Tagus: one of the principal rivers of Spain. It rises in the Sierra Albarracin, in lat. 40° 38' N., lon. 1° 35' W., flows mostly W. and S. W. through Spain and Portugal, and empties into the Atlantic at Lisbon, after a course of 566 miles. It is navigable 115 miles from its mouth.

Tahiti, *taä-hee'tée*, or *Otahel'te*: the largest of the SOCIETY ISLANDS (*q. v.*); in the Pacific Ocean, in lat. 17° 29' S., lon. 149° 29' W. It is high, reaching 7,336 feet at its highest point, but traversed by beautiful and fertile valleys, in which all tropical plants grow luxuriantly. It is 120 miles in circumference, with an area of 401 sq. miles, and had, in 1889, 9,603 inhabitants, who have been converted to Christianity. It is the principal island of the French establishments in Oceania, and contains Papiiti, the capital of the colony. See Dora Hort, *Tahiti, the Garden of the Pacific* (1891). Revised by M. W. HARRINGTON.

Tahlequah: town (founded in 1840); capital of the Cherokee Nation, Indian Territory; in the valley of the Illinois river; 26 miles E. of the Mo., Kan. and Tex. Railway, and 65 miles N. W. of Fort Smith, Ark. (for location, see map of Indian Territory, ref. 2-G). It is in an agricultural region, and contains national Cherokee schools, Female Seminary (building cost \$100,000), Male Seminary (building cost \$80,000), Capitol (cost \$20,000), Baptist and Presbyterian mission schools, 2 school libraries, a private bank, and 4 weekly newspapers (2 printed in English and 2 in both English and Cherokee). Pop. (1895) about 3,000.

EDITOR OF "TELEPHONE."

Tahoe, **Lake**: a lake partly in Nevada and partly in California, at an elevation of 6,225 feet in the Sierra Nevada. Its maximum length from N. to S. is 22½ miles and its greatest width 13 miles; area, 195 sq. miles; hydrographic basin, 500 sq. miles. Soundings by Prof. John Le Conte gave a depth of 1,506 feet, but it is thought that a more detailed survey will show a greater depth. Its waters are wonderfully clear, and are inhabited by excellent trout and other fishes. It is the source of Truckee river, which empties into Pyramid and Winnemucca Lakes. Surveys have been made with the view of drawing off its waters through a tunnel, for irrigation purposes. See *Physical Studies of Lake Tahoe*, by Prof. John Le Conte, in *Overland Monthly*, 1883 and 1884. ISRAEL C. RUSSELL.

Tahpanhes (Jer. xliii. 7-9), or **Tahpenes** (the *Tehaphnehes* of Ezek. xxx. 18, the *Δάφναι* of Herodotus, ii., 30, 107, and the *Τάφρη*, *Τάφραι* of the Septuagint): an Egyptian strong-

hold erected by Psammetichus I. as an eastern walled garrison for his Greek mercenaries, on the site of an earlier Ramesside town. It was to the E. what NAUCRATIS (*q. v.*) was to the W. of the Delta, and guarded the road to Asia. It was on the Roman road, 16 miles from Pelusium toward Memphis (*Itinerarium Antonini*, Wess. 162), on the Pelusiac branch of the Nile, at the present Tell Defenneh (30° 52' N. lat., 32° 8' E. of Greenwich). The main portion of the mound is known as the Palace of the Jew's Daughter (*cf.* Jer. xliii. 6-9), and its foundation deposits show that it was the work of PSAMMETICHUS I. (*q. v.*). A large elevated place before the fort has been identified with the "brick-work" in which Jeremiah hid large stones (Jer. xliii. 9) at the command of God. The site has furnished many Greek remains, but little that is Egyptian. In style the pottery of Tahpanhes was quite distinct from that of Naucratis, and shows attempts to imitate Egyptian bronze vases. This difference of style points to manufacture on the spot, not to importation from Greece. The date of the city is shown further by numerous impressions of the cartouch of Psammetichus I. on the seals of wine-jars. The overthrow of Hophra (Apries) by Amasis and the reduction of his eastern stronghold mark the existence of the place as from 665 to 564 B. C.

CHARLES R. GILLET.

Taillandier, *taä'yään'di-ä'*, RENÉ GASPARD ERNEST, generally known under the name SAINT-RENÉ TAILLANDIER: educator and author; b. in Paris, Dec. 16, 1817; studied philosophy and literature in Paris and Heidelberg; was appointed Professor of Foreign Literatures at Strassburg in 1841, at Montpellier in 1843, at the Sorbonne in 1863, and became in 1870 secretary in the department of public education. He was elected to the Academy in 1873. Besides poems, he wrote *Scot Érigène* (1843); *Histoire de la jeune Allemagne* (1849); *Études sur la Révolution en Allemagne* (2 vols., 1853); *Michel Lermontoff* (1856); *Maurice de Saxe* (2 vols., 1855); *Tchèques et Magyars, Bohème et Hongrie* (1869); *La Serbie* (1871); *Dix ans de l'Histoire d'Allemagne* (1875); *Le roi Léopold et la reine Victoria* (2 vols., 1878). D. in Paris, Feb. 24, 1879. Revised by A. G. CANFIELD.

Tailor: the BLUEFISH (*q. v.*), *Pomatomus saltatrix*. The name is also applied (usually in the form tailor-herring) to the fall herring, *Clupea* (or *Pomolobus*) *mediocris*. It is probably applied to the bluefish on account of its sharp cutting teeth, but its applicability to the herring is not apparent.

Tailor-bird [so called from its habit of sewing together the tips of two or three leaves to make a nesting-place]: a small bird (*Sutoria sutoria*), a representative of the family *Luciniidae*; found in India and other eastern countries. It is about 5 inches long, with a slender and slightly decurved bill, short and rounded wings, and very long tail composed of narrow feathers; olive green above and white beneath, and brick-red on top of the head. For its nest, generally two leaves at the end of a bough are brought in contact, and sewed together by the bill, vegetable fibers being used as the threads; sometimes a large leaf is rolled together and sewed at its margins. Within the cavity thus formed are deposited soft downy or cotton-like vegetable substances, and the nest is then completed for the reception of the eggs, of which six to eight are laid. Revised by F. A. LUCAS.

Tainan, *tä'naän'*: the name given to the treaty-port of Taiwan-foo in Formosa since it ceased to be the capital of the department and of the province of Taiwan. (See TAIWAN-FOO.) Pop. about 135,000. Tainan imports cotton and woolen goods, opium, metals, medicines, kerosene oil, ginseng, cuttlefish, rice, flour, gunny-bags, silk piece-goods, and matches; and exports sugar, camphor, hemp, lung-nan pulp, and turmeric. In 1893 the net foreign imports amounted to 1,596,166 haikwan or custom-house taels (= \$1,675,974), of which 92 per cent. came from Hongkong, while the net native imports amounted to 127,852 taels. The total exports amounted to 1,648,220 taels (= \$1,730,631), including 480,529 piculs of sugar, valued at 1,272,757 taels, and 5,934 piculs of camphor. In the same year 70 steamers and 14 sailing vessels (aggregating 53,686 tons) entered port, and 69 steamers and 12 sailing vessels (aggregating 52,443 tons) cleared. R. L.

Taine, HIPPOLYTE ADOLPHE: philosopher and historian; b. at Vouziers, Ardennes, France, Apr. 21, 1828; was educated at the Collège Bourbon and the École Normale of Paris, and became a teacher, but soon gave it up because of the hostility of the authorities in consequence of his ideas. His *Essai sur l'Intelligence* (1854) and *Les Philosophes français*

de XIX^e siècle (1858) attracted much attention by their sagacity and their sharp criticism of the current philosophy of Comte's school. Strongly influenced by the study of the natural sciences, he sought to apply rigidly to the whole range of human achievements the laws of heredity and environment. He regarded all products of human activity as determined by three factors, environment (*milieu*), race, and heredity. His works include *Enquête sur nous* (*Les Pygmées* (1855); *Ames de l'extinction d'histoire* (1857); *Les Pygmées de nos jours* (1859); *Histoire de la littérature anglaise* (4 vols., 1861); *Nouveaux essais de critique et d'histoire* (1862); *Philosophie de l'art* (1863); *Philosophie de l'art en Italie* (1864); *Voyage en Italie* (2 vols., 1869); *Les opinions de Thomas Hume* (1867); *Philosophie de l'art sous les Pays-Bas* (1868); *De l'intelligence* (2 vols., 1870); *Notes sur l'Angleterre* (1872); *Origines de la Prusse contemporaine* (undated, 5 vols., 1876-80). In 1884 he became Professor of Aesthetics at the School of Fine Arts, Paris, and in 1879 a member of the Academy. D. in Paris, Mar. 5, 1905. See *Acad. Marguerite, II. Tiers* (Paris, 1894); G. Monod, *Les Maîtres de l'histoire* (Paris, 1894). A. W. CAMPBELL.

Tai-ping (or **Tai-ping**) **Rebellion**, a formidable insurrection which broke out in 1850 in South China, and had for its object the overthrow of the Manchu dynasty, which had ruled since 1644, and the establishment of a new purely native dynasty, to be styled the dynasty of "Great Peace." Hence the name *Tai-ping* applied by foreigners to the rebels, who, however, were by the Chinese called *Ching-chang-tai* or "long-haired rebels," from the fact that they had discarded the queue or outward expression of allegiance to the Manchus. (See CHINA.) The leader of the movement, a Hakka schoolmaster named Hung-Siu-Kuen, born in 1814, also included in his plans the establishment of a corrupt kind of Christianity elaborated by himself partly from a vision he had had in 1837 during a period of illness, and partly from an imperfect study of some Christian tracts and books he had obtained some years before. In this vision he thought he was taken to heaven, where, having been "washed" by an old woman, some venerable sages opened his body with a knife, took out his heart and other parts, and put new parts in their place, and a venerable man with a golden beard addressed him, saying: "All human beings in the world are polluted and sustained by me; they eat my food and wear my clothing, but not one among them has a heart to venerate and remember me; they take my gifts and therewith worship demons; they rebel against me and arouse my anger," and giving Hung a sword he commanded him to "exterminate the demons." In his vision he also saw a man of middle age, whom he called his Elder Brother, and who instructed him how to act. After rereading the Christian tracts and books in Chinese which he had obtained, he concluded that the old man was God, the "Heavenly Father," that the middle-aged man was Christ, the "Heavenly Elder Brother," and that the demons were idols, and he became convinced that he had been appointed to restore the world to the worship of the true God. He at once began preaching his new beliefs, and thousands were converted. A "Church of God" was established, and so zealous were its members in demolishing temples and idols that they were soon brought into conflict both with their neighbors and with the authorities, and many fights ensued. In 1850 they broke out into open rebellion, Hung taking the name of the "Heavenly King." Early in 1852 they moved into Hunan, advanced down the Yang-tze, down which they sailed, capturing every important city on its banks; made Nanking their capital, threatened Peking, and carried destruction and death over fifteen of the eighteen provinces of China. It has been estimated that 20,000,000 lives were sacrificed in this struggle. It was not till 1864, when Nanking was recaptured on July 19 by the Ever-Victorious army under "Chinese" Gordon, that the movement began to weaken; Hung himself had already taken poison, and his principal generals had fled. The remnant under Tsen Wang made a last stand at Chung-kuo-fu in Fukien, but were pressed so hard by the imperialists that they had to withdraw and disband. The imperial operations were directed by Tsing-kuo-fan and Li Hong-Chang, but without the assistance rendered by the British and French at Shanghai and elsewhere, and by the native army drilled and officered by foreigners and led successively by Ward, Burgevine, Holland, Cooke, and Gordon. It is questionable if they would have succeeded in crushing the movement. See *Wells Williams's Middle Kingdom* (2 vols., New York, 1885). R. L.

Taira (Taira) a Japanese family descended from the Emperor Kammu, and all-powerful in Japan during the eleventh century. This was a period of great corruption at court, and of intrigue and conspiracy in the provinces. The family was the first that rose to a leading place in the state by military prowess. Its chief representative was Kiyomori, who after triumphing over the rival Minamoto party in 1189, was able to make and unmake emperors at will. When he died in 1189 only some infants of the rival clan had been spared, one of whom, however, Yoritomo (q. v.) was destined to restore the fortunes of his family and form the Taira dynasty. The incidents of these troublous times furnish to native art an inexhaustible store of themes for treatment. J. M. DELOS.

Tait, ARCHIBALD CAMPBELL, B.D., LL.D., archbishop, b. in Edinburgh, Scotland, Dec. 22, 1811; educated at the high school and academy in Edinburgh, at the University of Glasgow, and at Balliol College, Oxford, where he became public examiner; was one of the leading opponents of the Tractarians or Puseyites; took orders in the Church of England; was head master of Rugby school from 1842 to Apr., 1850, when he accepted the bishopric of Carlisle, succeeded Dr. Blomfield as Bishop of London Aug., 1860; originated in 1861 the successful scheme of raising a fund of £1,000,000 for supplying the deficiencies of church accommodation in London; succeeded Dr. Langley as Archbishop of Canterbury in 1865. He was the author of *The Dangers and Safeguards of Modern Theology* (1861) and *The Word of God and the Ground of Faith* (1864), besides addresses, sermons, etc. D. in London, Dec. 3, 1892. See the *Life* by Davidson and Benham (2 vols., 1891).

Tait, LAWSON, M.D., LL.D., gynecologist, b. in Edinburgh, Scotland, in 1845; studied arts and medicine in the University of Edinburgh 1859-66; settled in Birmingham, England, in 1870; passed the examinations for fellowship in 1866, and in 1870 was made honorary fellow of the Royal College of Surgeons, Edinburgh; passed the examinations for member in 1870, and for fellow in 1871, of the Royal College of Surgeons, England. He is one of the foremost surgeons in abdominal operations in Great Britain. His most important work, *Diseases of Women*, has passed through several editions. S. T. ARMSTRONG.

Tait, PETER GUTHRIE, physicist and mathematician, b. at Dalkeith, Scotland, Apr. 25, 1831; educated at Edinburgh University and at St. Peter's College, Cambridge, where he graduated as senior wrangler in 1852; became Professor of Mathematics in Queen's College, Belfast, in 1864, and Professor of Natural Philosophy in Edinburgh University in 1866. He has written a number of monographs on the kinematical theory of gases, thermo-electricity, thermal conductivity, refractive, etc., and in pure mathematics on knots and quaternions. He is the author of *Dynamics of a Particle* (1866), written in conjunction with Steele, a work which has run through many editions; *Elementary Treatise on Quaternions* (1867); *Thermodynamics* (1868); *Recent Advances in Physical Science* (1870); and *Mathematical Philosophy* (1875); besides several text-books on physics, written in a direct, lucid, and forcible style. In conjunction with Lord Kelvin he wrote the *Treatise on Natural Philosophy*, and with Balfour Stewart *The Unseen Universe*. R. A. R.

Taiwan, T'wân' (literally, terminal bay); the Chinese name of the large island lying off the coast of Fukien, China, which is by foreigners called Formosa (q. v.). Until 1895, when it was made a separate province, it was a department of Fukien, with a tai-tai or intendant of circuit at its head, and was divided into four *hien*, or districts, and five seacoast divisions called *ling*. Beginning at the S. and proceeding N. the *hien* are: *Peng-shan-hien*, *Taiwan-hien*, *Kia-yi-hien*, and *Ching-huo-hien*. The *ling* are: *Taijung-ling*, comprising the seaboard of Peng-shan *hien* and Taiwan-hien; *Lan-kang-ling*, the seaboard of the two remaining *hien*; *Tsu-shan-ling* (or *Tsinan-ling*), the whole of the northernmost portion on the west side of the island; *Kap-shan-ling*, the whole eastern part of the island; and the *Peng-shan-ling*, comprising the group of islands lying off the west coast, and known as the Pescadores. Tainan, a few miles from Kiloang, has been the capital since 1895. By the treaty concluded at Hiroshima, Japan, early in 1895, China ceded Taiwan to Japan, and the Japanese took possession of it early in June, 1895, though opposed by the so-called republic which had been proclaimed there by the Chinese soldiers and residents some weeks earlier, with Tang, the ex-governor, as president. R. L.

Taiwan-foo: a walled city of Formosa and a treaty-port: situated on the west coast of the island, in about lat. 23° N. and lon. 129° E. (see map of China, ref. 8-K). Until 1885 it was the capital of the island and the residence of the chief civil and military officials. Since 1886 it has been called TAINAN (*q. v.*). It stands on a level plain of considerable extent, about 3 miles from the sea, from which canals run right up to the west gate, so that merchandise can be landed from ships in the roadstead alongside the godowns or storehouses in the western suburb, where most of the business is carried on. Kok-si-kon, the port of Taiwan-foo, 3 miles distant, is an open roadstead, in which ships anchor about 3 miles from shore. It is fairly well protected for vessels in the northeastern monsoon, but unsafe during the southwestern monsoon. For trade statistics, see TAINAN. Between this western suburb and the sea is the village of Anping, near which are found the ruins of the famous stronghold called Zelandia, built by the Dutch in 1624-30, when they established themselves on the island. It consisted of a single keep on a small hill, in the form of a bastioned fort, with another wall on the northern side at a distance of 100 yards. The walls were of great thickness and were built of small bricks, brought from Batavia for this special purpose. R. L.

Tai-yuen: a walled city of China, capital of the province of Shansi, but of no commercial importance (see map of China, ref. 4-I). It lies between two hills near the head of a fertile plain of considerable extent, about 3,000 feet above the level of the sea, and consists, like Peking, of an inner and an outer city, but has no extra-mural population. The outer city is surrounded by mud walls, pierced for three gates, but only two are opened. The inner city, or city proper, which is 2½ miles long by 1½ wide, has walls of moderate height pierced with eight gates surmounted by fine towers. The streets are 50 to 75 feet wide, and the people are well-behaved. Tai-yuen has a powder-mill and an arms-factory, and was anciently noted for its sword-blades and knives. Pop. about 200,000. R. L.

Takashi'ma: an island of Japan; about 8 miles from the entrance to Nagasaki harbor. It is only 250 acres in extent, and was, until a comparatively recent date, uninhabited. Coal-mining operations on a primitive scale were begun before the middle of the eighteenth century; in 1867 Scottish miners were employed, and now (1895) several thousand workmen turn out the largest output of any coal mine in Asia. At one time it was feared that the supply was near exhaustion, but later new veins were discovered and the output is undiminished. The mines extend for a considerable distance under the sea. J. M. Dixon.

Takata, taa-kua taa: a town in the province of Echigo, Western Japan; about 4 miles from the seacoast and 74 miles S. W. of Niigata (see map of Japan, ref. 5-D). Its port, Naoetsu, is the western terminus of the railway from Tokio to the west coast. It was formerly the castle-town of a daimio, Sakakibara, one of the four families entitled to supply a regent during the minority of a shogun. Cotton-weaving is extensively carried on, as also are leather-working and furriery. The Presbyterians of the U. S. have a mission here. Pop. 28,000. J. M. D.

Takil'man Indians: a stock of North American Indians, represented, so far as is known, by only one tribe, the Takélma. Their habitat was on the upper part of the Rogue river, Oregon (whence they are called Rogue River Indians), and their villages, numbering seventeen, extended along the south side of the river from the valley of Illinois creek to "Deep Rock," probably Rock Point, E. of Woodville, in Jackson County. It is probable that they were once the occupants of a territory larger than that just described, and that later there was an invasion by the Athapascan Indians, who established villages on all sides of them and imposed Athapascan names on Takilman villages, though they never succeeded in forcing the Takélma to abandon their own language. The present representatives of the tribe number about twenty-five, and are on the Siletz Reservation, Tillamook co., Ore. Apparently the Takilman Indians differed in no essential respect from their neighbors, except in their language. J. OWEN DORSEY.

Takow, taa'kow: a town on the west coast of Formosa: lat. 22° 38' N., lon. 130° 16' 30" E.; about 20 miles S. of Taiwan-foo (see map of China, ref. 8-K). It was thrown open to foreign residence and trade in 1864, but its trade has never been great. The custom-house returns are included in those of Taiwan-foo, now called TAINAN (*q. v.*).

Taku, taa'koo': a Chinese village, situated at the mouth of the Pei-ho, on the right or south bank; about 70 miles by water from Tientsin, but only 35 by land (see map of China, ref. 3-J). Here are situated the famous Taku forts, which, though deemed impregnable by the Chinese, were taken three times by the Anglo-French fleets in the campaigns of 1858-60. See Oliphant's *Narrative of Lord Elgin's Visit to China in 1857-58-59*, and Swinhoe's *North China Campaign of 1860*. R. L.

Talavera de la Reina, taa-laa-vā rāa-dā-laa-rā-ee-nāa: an old but well-built town in the province of Toledo, Spain: on the Tagus, 75 miles by rail S. W. of Madrid; in an exceedingly fertile plain, covered with vineyards and olive-groves (see map of Spain, ref. 16-E). It has manufactures of silk and earthenware. Here was fought a severe battle on July 28, 1809, between the French under Jourdan and Victor, and the allied Spaniards and British under Sir Arthur Wellesley (afterward Duke of Wellington), in which the latter were victorious. It was the birthplace (1536) of the historian Mariana. Pop. about 10,500.

Talbot, RICHARD: See TYRCONNEL.

Talbot, SILAS: naval officer; b. at Dighton, Bristol co., Mass., in 1751: at the beginning of the war of the Revolution was made captain in a Rhode Island regiment, and was present at the siege of Boston; in 1776 accompanied the army to New York, where he planned an attack by fire-ship on the British shipping, for which he received a commission as major and the thanks of Congress; was severely wounded in 1777 during an engagement with British vessels in Delaware river, and in 1778 he captured the British blockading schooner the Pigot, and was appointed captain in the navy Sept., 1779; fitted out the Pigot and captured several prizes, but in 1780 was made prisoner and sent to England; was exchanged in Dec., 1781; settled in New York, and in 1793-94 was in Congress; when the navy was reorganized in 1794 he superintended the construction of the frigate Constitution, which was his flag-ship during a cruise in the West Indies in 1799. D. in New York, June 30, 1813. See the *Life* by Henry T. Tuckerman (1850).

Talbot, WILLIAM HENRY FOX, LL. D.: photographer and antiquarian; b. at Lacock Abbey, near Chippenham, England, Feb. 11, 1800; graduated at Cambridge 1821; sat for Chippenham as a Liberal in the first reformed Parliament 1832-34; pursued for some years from 1833 a series of experiments which resulted in Sept., 1840, in the discovery of the essential principle of the art of photography, and in 1841 of the calotype process; received in 1842 a medal from the Royal Society, and in later years devoted himself to antiquarian pursuits and philological studies, being one of the few scholars who have successfully deciphered the Assyrian cuneiform inscriptions. Among his works are *Hermes, or Classical and Antiquarian Researches* (vol. i., 1828; vol. ii., 1839); *Legendary Tales in Verse and Prose* (1830); *The Antiquity of the Book of Genesis illustrated by some New Arguments* (1839); *The Pencil of Nature, a Collection of Genuine Specimens of the New Art of Photography* (6 parts, 1844-46). D. at Lacock Abbey, Sept. 17, 1877.

Talbotype: same as calotype. See PHOTOGRAPHY.

Talc [from Fr. *talc*, from Arab. *'talaq*]: a magnesium silicate, usually somewhat hydrated, which sometimes makes up the mass of geological formations. Talc, when crystallized, is right rhombic. It belongs to the softest minerals, ranking with graphite in this respect, and is used as the lowest member, No. 1, of the scale of hardness. It is seldom found well crystallized, but usually in compact or in foliated masses, the foliation arising sometimes from the cleavage of the mineral, which is micaceous in its character. Its usual color is a light green, due to ferrous oxide associated with the magnesium base; but this color and this constituent are not essential, and it is found perfectly white, sometimes with a silvery luster. The massive varieties are called soapstone. (See STEATITE.) The average composition of the commoner varieties of talc is stated as $O_2Si_2Mg_3$, $2H_2O$; but there is an anhydrous talc, not separated from this species by Dana and other authorities, which, according to analyses of Genth, Senft, Lychnell, and Kersten, computes distinctly to the formula $O_2Si_2Mg_3$. Dana suggests that quartz may have been present as an impurity in these; but this would not account for the entire absence of water from many of the analyses; and, moreover, the density would be diminished by quartz, whereas one of Lychnell's anhydrous talcs gave the maximum density of all, 2.795.

On other extremes of the range of anthropometric densities is a hydrous tale, a muscovite from Charleston Lake, Ontario, for which Störrer gives the figure 2444.

Talca, a province of Chili, out by the thirty-sixth parallel of north latitude; extending from the Pacific to the Argentine frontier. Area, 3,978 sq. miles. The Andes, including the quiescent volcanoes of Hornos and Corra And, occupy the eastern part; those and the lower Cordillera have forests resembling those of the southern provinces. The intermediate space consists of plains and rolling lands of great natural fertility, and improved by irrigation. The river Maipo forms the southern boundary. The principal industries are wheat-raising and grazing. Pop. (1901) estimated, 149,734. Talca, the capital, is in a fertile valley, watered by a branch of the Maipo, on the railway from Chillan to Santiago, with a branch to the port of Constitución on a map of South America, ref. 9-C). It is well built, has a seminary, hospital, etc., and is the center of a thriving trade. The climate is disagreeable, owing to the unusual extremes, for Chili, of heat and cold. Pop. (1905) 23,423; in 1905 probably over 30,000.

HERBERT H. SARRIS.

Talcott, ADAM W., civil engineer and mathematician; b. at Philadelphia, Penn., Apr. 20, 1797; graduated at the U. S. Military Academy July 24, 1815, when appointed brevet second lieutenant in the Corps of Engineers. After a year's service on construction duty, he accompanied Gen. Henry Atkinson, as engineer, on the expedition to locate military posts on the upper Missouri and Yellowstone rivers, and on his return was assigned to the construction of the defenses of Hampton Roads, Va., Fort Delaware, etc., until 1835; from 1833 to 1839 was also engaged as astronomer for determining the boundary-line between Ohio and Michigan, and was in charge of the improvement of the Hudson river 1834-36; resigned from the army Sept. 21, 1836, to become division engineer on the Erie Railroad; in 1837 returned to duty in a civil capacity under the Government as superintendent of the improvement of the docks of the Mississippi river 1837-39; member of commission for exploration and survey of the northeastern boundary of the U. S. 1840-43; of joint army and navy board to visit the Portsmouth and Pensacola navy-yards and prepare plans for dry docks and other important works 1844-45; from 1848 to 1853 was chief engineer of the Richmond and Danville Railroad; of the Ohio and Mississippi Railroad 1856-57; of the railway from Vera Cruz, via the city of Mexico, to the Pacific Ocean, nearly completing the road from Vera Cruz to Mexico. He devised what is known as Talcott's method for determining territorial latitudes by the observation of stars near the zenith. D. at Richmond, Va., Apr. 22, 1885.

Talent [via G. Fr. from Lat. *talens* *lumen*, from Gr. *talantos*, a certain weight, a certain weight of silver or gold, talent of money, liter, a balance. Cf. *talos*, bear, endure, Lat. *tolere*, lift, Sarskr. *talā*, balance;] an ancient Greek weight containing 63 minas, about 82 lb. avoirdupois. There was a Babylonian and an Egyptian talent, which were in the Attic as 5 to 6; the Babylonian talent was to the Attic nearly as 4 to 3; the Tyrian was equal to the Attic; the Cilician was half the Attic, etc. There was also a gold or Sicilian talent of about three-fourths of an ounce avoirdupois, called also the little talent. A talent in money was originally a talent's weight of silver or of gold, but the talent finally became a money of account. It was among all the Greeks the monetary unit. Its value varied with the kind of talent used and with the purchasing power of gold and silver. The Attic silver talent was smaller than the commercial talent, weighing 57 lb. of silver.

Talford, tal'ford, Sir Thomas Noon; statesman and author; b. at Doxey, near Stafford, England, Jan. 26, 1759; was the son of a wealthy brewer; studied at the Reading dissenting grammar school under Dr. Valer; was entered at the Middle Temple; studied law with Chitty, the celebrated pleader, and was called to the bar in 1821; practiced on the western circuit, sitting at the same time as law reporter for the *London Times*; in 1823-24, and again in 1847-49, was a member of Parliament for Reading, and in 1849 was made a judge of the common pleas. In Parliament he was especially distinguished for his advocacy of the *Control of Infants Act* and of the *Copyright Act* of 1842. He published many speeches and essays, some of which have been collected under the title *Political and Miscellaneous Essays of Thomas Noon Talford* (1842). Among his works are *Tracts on Various Subjects* (1813); *An Attempt to Estimate the Political Talent of the Present Age* (1815), one of

the earliest public tributes to the genius of Wordsworth; *History of Greek Literature*, *History of Greece*, and *History of the Human Republic*; several distinct volumes relating to his intimate friend Charles Lamb, subsequently put forth as one work, *Memories and Correspondence of Charles Lamb* (1807); *Final Moments of Charles Lamb* (1845); *Four Imaginations* (1822); *The Abbeville Captive* (1809); *Obsequies* (1808); and *The Justices* (1866), the first two of which had a stage success; *Reminiscences of a First Visit to the Alps* (1842); *Vacation Rambles* (1844); and *Supplement to Vacation Rambles* (1846). D. at Stafford, Mar. 18, 1824.

Revised by H. A. REANS.

Tallesia, tal'esi-a, a Welsh bard, said to have flourished during the twelfth century, whose name has been handed down, together with that of the two Morlins, as the three principal Christian bards, Tallesia being styled *Iar Iorodd*, the chief of the bards. Many compositions ascribed to him are preserved in the *Archology of Wales*.

Tallipes. See *Cyclopædia and Oceanographic Survey*.

Talipot [from Hind. *tāpat* = Sanskr. *tālapatta*, palm-leaf; *tala*, palm-tree; *patta*, leaf] a palm-tree, *Corypha umbraculifera*. It affords great leaves, which are used for covering houses, making umbrellas, and for making a substitute for writing-paper that is used extensively in the East, as well as for many other purposes. The pith affords a kind of sago. The tree grows in Malabar and Ceylon.

Talladega, city; capital of Talladega co., Ala.; on the River and Atl. the Lumber, and Nashville, and the South, railways; 28 miles E. of Birmingham, 90 miles S. W. of Anniston (for location, see map of Alabama, ref. 4-D). It is in an agricultural and mining region, and is noted for its educational and public institutions, which include the Talladega College for Negroes (Congregational, chartered in 1899), Isbell Female College for whites, Talladega Military Academy for whites, Alabama Institution for the Deaf (whites), Alabama Academy for the Blind (whites), Alabama Institution for the Colored Deaf, Dumb, and Blind, several public schools, and an Orphan's Home. The city has Baptist Congregational, Methodist Episcopal, Presbyterian, and Protestant Episcopal churches, 2 national banks with combined capital of \$100,000, cotton-factory, tannery, and 3 weekly newspapers. On the site of Talladega Gen. Jackson gained a victory over the Creek Indians in 1813. Pop. (1880) 1,254; (1890) 2,033; (1905) estimated, 4,000.

EDITOR OF "OUR MODERN HOME."

Tallahassee, city; capital of the State of Florida and of Leon County; on the Carrabelle, Tall and Fla., and the Fla., Cent. and Pen. railways; 21 miles N. of the Gulf of Mexico, 165 miles W. of Jacksonville (for location, see map of Florida, ref. 2-F). It is in an agricultural and fruit-growing region; contains 4 churches for white people and 6 for colored, separate public schools for white and colored children, West Florida Seminary, Normal College for Colored Teachers, 2 libraries (State, founded 1845; University, founded 1884), U. S. Government building, a national bank with capital of \$50,000, a State bank with capital of \$20,000, a private bank and a weekly newspaper; and has railway car-shops and machine and novelty wood works. Pop. (1880) 2,494; (1890) 2,934; (1905) estimated with suburbs, 5,000.

EDITOR OF "WEEKLY TALLAHASSEEAN."

Tallahatchie River: a river which flows in Tippah co., Miss. After a devious course of more than 250 miles, it is generally S. S. W. direction, it unites with the Yallogassee to form the Yazoo. Throughout more than half its extent it is navigated by steamboats at all stages of water.

Tallapoosa, city; Barlow co., Ga.; on the Southern Railway; 34 miles from the Tallapoosa river, 63 miles W. of Atlanta; elevation, 1,290 feet above sea-level (for location, see map of Georgia, ref. 2-F). It is in an iron, timber, agricultural, and fruit-growing region, and contains six churches, free graded schools for white and colored pupils, a State bank with capital of \$57,500, and a weekly newspaper. Adjacent to the city are about 3,000 acres devoted to grape-culture. The prosperity of the city dates from 1897, and is due to Northern capitalists. Pop. (1890) 1,699; (1905) estimated, 3,600.

EDITOR OF "JOURNAL."

Tallapoosa River: a river which rises in Paulding co., Ga., and joins the Coosa to form the Alabama river. It is 250 miles long and is navigable by steamboats some 40 miles.

Talleyrand-Périgord, Pé. pron. tal'á'ránd'pé'ré'gór; CHARLES MATHIEU, Duc de, Prince of Benevento; states-

man; b. in Paris, Feb. 13, 1754; was compelled by his family to renounce his right of primogeniture on account of his being lame, and was educated for the Church. He studied at St.-Sulpice, the Sorbonne, and at Rheims, and attracted much attention by his wit and other brilliant gifts. In 1775 he was ordained priest in spite of the notorious licentiousness of his life, in 1780 was chosen agent-general for the clergy, and in 1789 the king made him Bishop of Autun. Elected a deputy to the States-General, he was one of the first of the clergy who joined, and prompted his colleagues to join, the *tiers état*, and in intimate harmony with Mirabeau and Sieyès he took a prominent part in the debates of the Assembly. On Oct. 10, 1789, he proposed the confiscation of all Church property; July 14, 1790, he officiated at the grand national festival in the Champ de Mars, and consecrated the new colors of the national guard; Dec. 28, 1790, he took the oath to obey the constitution, and when the pope excommunicated him (May 1, 1791) he resigned his episcopal see. In the Representative Assembly his speeches on financial, educational, and other reforms exercised great influence. Nevertheless, a rumor was circulated that he was conspiring with the Duke of Orleans, and his friends saved him by procuring for him a diplomatic mission to London. While there his name was placed on the list of *émigrés*. He lived for some time in London and afterward in the U. S., but returned to Paris in 1796, and became Minister of Foreign Affairs in July, 1797, which office he held to Aug., 1807, with one short interruption. Recognizing the force of Napoleon's character, he gave him his support loyally in his struggle for power. He negotiated all the various treaties of peace of this epoch—the concordat with the pope, who relieved him from excommunication and secularized him; the confederacy of the Rhine, after which he was made Prince of Benevento, etc.; but he disapproved Napoleon's policy toward Great Britain, opposed his plans with respect to Spain, and when, after the Peace of Tilsit, an alliance was formed between France and Russia, he resigned his office and retired to his estates at Valençay. Before the Russian disaster he predicted the downfall of Napoleon, and entered into communication with the Bourbons; and during the last three years of Napoleon's career he was one of his most active and most dangerous enemies. He negotiated the first Peace of Paris, and represented France at the Congress of Vienna. Here he succeeded in dissolving the general feeling of concord with which the powers met, and produced a confusion of jealousy, mistrust, rivalry, and hatred which he understood how to use to the advantage of France. After the second restoration, however, he fell into disgrace, and during the reigns of Louis XVIII. and Charles X. took very little part in public life. In Sept., 1830, Louis Philippe sent him as ambassador to London, and he succeeded in establishing cordial and intimate relations between the courts of St. James and the Tuileries, and concluded the quadruple alliance between Great Britain, France, Spain, and Portugal Aug. 22, 1834. He returned to France shortly after. D. at Valençay, May 17, 1838. His *Mémoires* were intended by him to be published thirty years after his death, but in 1868 the publication was postponed for twenty-two years on the proposition of Napoleon III. They were published in 5 volumes 1889-91. For an account of his course at the Congress of Vienna, see *Correspondence between Talleyrand and Louis XVIII.* (1881); for estimates of his character, Lamartine, *Mémoires Politiques*; Blanc, *Histoire de Dix Ans*; Guizot's *Mémoires*; and Bastide, *Vie Religieuse et Politique de Talleyrand*. Revised by F. M. COLBY.

Tallien, tā'li-ān', JEAN LAMBERT: revolutionist; b. in Paris in 1769; became noted in 1792 as the editor of a Jacobin journal, *L'Ami du Citoyen*; was elected a member of the Convention; advocated the condemnation and immediate execution of Louis XVI., and attacked the Girondins with senseless fury. In 1793 he was sent to Bordeaux to exterminate the moderate party, but here he became acquainted with Madame de Fontenay, one of the most attractive women of that time, and this acquaintance suddenly changed him from an extreme radical to a decided moderate. He was immediately recalled, his name was erased from the lists of the Jacobin Club, Madame de Fontenay was thrown into prison, and his own life was endangered; but in this emergency he rallied the partisans of Danton and Hébert, and by his energy and coolness at the decisive moment the overthrow of Robespierre and the Terrorists was accomplished July 27, 1794. He then became one of the most conspicuous figures in the republic, and

married Madame de Fontenay. He became a member of the Council of Five Hundred, but, trusted by neither monarchists nor republicans, was forced to withdraw. He went with Bonaparte to Egypt as a *savant*, but quarreled with Gen. Menou and was sent back to France in 1800. He was captured by a British cruiser and taken to London, where he was feasted and flattered by the Whig party as a hero. He returned to France in 1802, and died in Paris, Nov. 16, 1820. F. M. COLBY.

Tallis, THOMAS: organist; b. about 1520; was perhaps organist to Henry VIII., and certainly gentleman of the chapel to Edward VI., Mary, and Elizabeth, and organist to the last named; and has been styled the father of English cathedral music. In conjunction with his pupil, William Byrd, he issued *Cantiones quæ Sacrae vocantur*, etc. (1575), which are masterpieces, and were protected for twenty-one years by Elizabeth, this being the first patent of the kind granted by her. There are also extant his *Order of Daily Service* (ed. by Bishop, 1843, and by Rimbault, 1847), *Full Cathedral Service* (ed. by Rimbault, 1847), and *Order for Morning Prayer, with the Litany Noted* (new ed. 1854). It is said that for portions of his *Service* he was indebted to Peter Marbeck, organist of Windsor. D. Nov. 23, 1585. A complete list of his works is in Grove's *Dictionary of Music*.

Tallmadge, BENJAMIN, M. A.: soldier; b. at Setauket, N. Y., Feb. 25, 1754; graduated at Yale in 1773; principal of a high school at Wethersfield, Conn.; entered a Connecticut regiment at the outbreak of the war of the Revolution; rose to the rank of major; performed a brilliant exploit in crossing Long Island Sound, surprising and capturing 500 Tories at Lloyd's Neck, L. I., Sept. 5, 1779; planned and executed the capture of Fort George at Oyster Bay and the destruction of British forces on Long Island, May, 1780; was engaged in several prominent battles; was entrusted with the custody of Maj. André, and superintended his execution; was a member of Congress 1801-17. D. at Litchfield, Conn., Mar. 7, 1835. His *Memoirs* were published in 1859 by his son, Frederick A. Tallmadge.

Tallmadge, FREDERICK AUGUSTUS: lawyer; son of Benjamin Tallmadge; b. at Litchfield, Conn., Aug. 29, 1792; graduated at Yale College 1811; studied law under Judge Tapping Reeve at Litchfield, where he was admitted to the bar; began practice in New York 1814; soon became one of the most successful advocates, and filled many public posts, including those of member (1837-40) and president of the State Senate, judge of the Supreme Court of Errors, recorder of New York 1841-46 and 1848-51, member of Congress 1847-49, superintendent of the metropolitan police 1857, and clerk of the court of appeals 1862-65. He became best known for the energy he displayed while recorder in suppressing the Astor Place riot of May, 1849. D. in New York, Sept., 1869.

Tallmadge, JAMES, LL. D.: lawyer; b. at Stamford, N. Y., Jan. 28, 1778; son of Col. James Tallmadge (1744-1821), an officer of the Revolution; graduated at Brown University 1798; studied law, which he practiced several years, but gave his chief attention to agriculture; was for some time private secretary to Gov. George Clinton; held a military command in New York during the war of 1812-15; was member of Congress 1817-19; introduced an amendment to the bill admitting Missouri excluding slavery from the region W. of the Mississippi; took a prominent part in the New York constitutional conventions of 1821 and 1846; sat in the Assembly 1824; was Lieutenant-Governor 1825-26. In 1836 introduced into Russia several American mechanical inventions, especially cotton-spinning machinery; was one of the founders of the University of the City of New York. D. in New York, Sept. 29, 1853.

Tallow [M. Eng. *taluh*: Low Germ. (hence Germ.) *talq*]: the hard fat of animals, more properly called suet. The term also includes those fats of a less degree of hardness, e. g. lard and grease, as distinguished from oils. The fats obtained from the rendering of animal fats of all kinds are technically known as tallow, and are chiefly used by the tallow-chandler for the production of soap and candles. The animal fats are hard in proportion as they contain more stearin and palmitin and less of olein. The quality of animal fats is much influenced by the mode of feeding and the quality of the food. The quality of tallow is also very dependent on its being rendered at a low temperature by steam, and the cleanliness of the operation, the character of the animals treated, etc.

Vegetable tallow is found in the seed of many plants. Chinese vegetable tallow is from the husk about the seeds of *Stillingia sebifera*; the berries contain a liquid fat. The seed commercial product is white, sp. gr. 0.918, and melts at 29° F.; it is rich in palmitin. Berry tallow, from *Mussaenda sebifera*, also called myrtle-wax, is a pale-green, brittle, solid fat from the berries of the plant. It resembles in the fingers like wax when warm. It contains myristic acid in a free state, and also combined with glycerol, and a large quantity of palmitic acid, but no oleic or volatile acids (*Mussey*). Other hard vegetable fats are found in nutmeg, palm oil, Japan wax, castor-oil, coccoline grains, and various species of *Rhus*, for a description of which see *Gmelin, Handbuch*, vol. 345-460. See also *Fats and Oils*.

Revised by IAN HANCOCK.

Tallow tree: (1) of the southern parts of the U. S. and of China, see *WILLIAMS*; (2) the *Podocarpus latifolius* of West Africa, a gulliform tree whose fruit yields a kind of yellowish tallow; (3) the pine dammar-tree of India, *Dipterocarpus*, a huge dipterocarpaceous tree, whose seeds on boiling yield an excellent white tallow.

Talma, Louis-Joseph, François-Joseph; tragedian; b. in Paris, Jan. 15, 1739, the son of a dentist; was educated partly in London, partly in Paris in his father's profession, but was irresistibly drawn to the stage, and made his debut in 1767 at the Comédie Française as Scile in Voltaire's *Métempsécosis*. His debut was successful, but he produced the first great impression by his performance of the title-role in Marie-Joseph Chenier's tragedy, *Charles IX.*, Nov. 4, 1769, from which date he rapidly rose in the estimation of the public until in the first decade of the nineteenth century he stood acknowledged by the whole world as the greatest tragedian of his time. He was a favorite with Napoleon, who liked to converse with him, and whom he accompanied to Erfurt in 1809, and to Dresden in 1810. The Bourbons also showed him great favor, and in his art he continued unrivalled and improving until his death Oct. 19, 1826, some of his last rôles, *Nelly*, *Oreste*, etc., being among his greatest creations. Before his time the tragic heroes, Brutus, Caesar, Lucius, Nero, etc., always appeared on the stage in a sort of fancy costume, not very different from the costume of the age, and with high powdered peruke on the head. Talma was the first to discard the peruke and adopt a correct costume. He wrote *Réflexions sur l'éloquence de sur l'art tragique* (1815), and left an *Autobiographie*, which was edited by Alexander Dumas in 4 vols. (1840-50).

Revised by B. B. VALLENTINE.

Talmage, Thomas De Witt, D. D.; clergyman; b. near Bound Brook, N. J., Jan. 7, 1812; educated, without graduating, in the class of 1834, University of the City of New York, and at New Brunswick Theological Seminary; pastor of Reformed churches at Belleville, N. J., 1836-39; Syracuse, N. Y., 1839-62; Second, Philadelphia, Pa., 1862-69; Central Presbyterian (since 1870 known as "Tabernacle"), Brooklyn, N. Y., 1869-94; began a popular Sunday afternoon service at the Academy of Music, New York, in 1895. During his pastorate in Brooklyn, the Schermerhorn Street church was opened as a Tabernacle lay college for training Christian workers, with Dr. Talmage as president; the Tabernacle was built in 1870, burned 1872; rebuilt 1874, burned 1880; rebuilt 1891, burned 1894; the membership last reported being 4,447. Dr. Talmage edited *The Christian* at West, New York, 1873-76; *The Advance*, Chicago, 1877-78; *Frank Leslie's Sunday Magazine*; and since 1890 *The Christian Herald*. His sermons appear every week in many hundred secular and religious papers, and are translated into many foreign languages. Besides frequent contributions to periodicals, including a series of articles describing his journey around the world in 1893-94, he has published *The Altar-stones in Babylon* (Philadelphia, 1870); *Shells of Turbulence* (New York, 1870); *Sermons* (4 vols., New York, 1872-73); *Announcements of Modern Society* (New York, 1873); 3d ed. 1876; *The Bullets for Brand*; *One Thousand Years*; or *Brilliant Passages and Anecdotes* (1873); *Old Wells Dug Out* (1874); *Around the Tivoli* (Philadelphia, 1874); *Orange Blossoms Frosted*; *Spirits that Kill* (New York, 1876); *Everyday Religion* (1875); *Night Sides of a City Life* (1877); *Mask Turn Off* (1878); *The Brooklyn Tabernacle*; 104 *Sermons* (1884); *The Marriage Ring* (1886); *Second Dynasty* (Chicago, 1887); *The Pathway of Life*; *From the Pyramids to the Acropolis* (Philadelphia, 1892); *Ready? Ay Ready!* (1892); and *From Manger to Throne* (New York, 1904).

C. E. HOLT.

Talmud (from *Hebrew*, *talmod*, instruction, deriv. of *lamed*, learn; cf. *Heb. talmud*, teach, *talmod*, discipline, scholar), a work whose authority was long esteemed second only to that of the Bible, and according to whose precepts the whole Jewish people, with the exception of the Karaites and the Reform Jews of the nineteenth century, have endeavored to order their religious life. In reality it is composed of two distinct works, which were compiled at different epochs—the Mishna and the Gemara. In the oldest terminology of the rabbis "Talmud" signified "a teaching," and designated the process of seeking in the sacred writings support for laws not expressly provided therein. On this account the Mishna which antedated these discussions was also known as Talmud. Later on, when learned disputations on the Mishna became more frequent, the name Talmud was employed to denote these more recent discussions in contradistinction to the Mishna proper. To later times they were called *Gemara* (the Aramaic equivalent of Talmud). It was only at a still later period, when the Mishna and the Gemara were no longer transmitted separately, that the name Talmud was applied to the whole great work consisting of both Mishna and Gemara.

(A) *Mishna*.—The name Mishna signifies simply repetition, teaching, doctrine. It was used to designate, first, each individual ordinance; secondly, a group of interconnected ordinances; lastly, and especially, the great compilation of ordinances now known by this name, the authorship of which is referred to Rabbi Jehoshua Hanasi. In the Talmud of Palestine, however, each individual Mishna is called *Halakhá*.

(a) *The Structure and Arrangement of the Mishna*.—It consists of six divisions (*Sedarim*): 1. *Zeraim*, laws relating to seeds and products of the fields; 2. *Moadim*, laws relating to the festival celebrations; 3. *Nashim*, laws relating to women; 4. *Negila*, civil and criminal laws; 5. *Kodshim*, laws relating to offerings and vows; 6. *Taharot*, laws relating to ritual cleanliness and uncleanness. Each division is subdivided into *Massekhtot* (*tracts*), of which there are 63 (11, 12, 7, 10, 11, 12). The whole number of tracts is occasionally given as 61, the first three tracts of the fourth division being counted as one; or as 60 (*Shit Hashirim Rabbim*, 6, 9; *Makoth* being counted as the last part of *Sederim*). Each tract is again subdivided into *Perekim* (chapters), of which the total number is 522 (74, 88, 71, 78, 91, 120), and each chapter into paragraphs. The order and sequence of the *Sedarim* are fixed and unaltered. The same uniformity, however, does not exist in the sequence of tracts and chapters, a slight divergence having been noted between the Mishna, the Palestinian, and the Babylonian Talmuds.*

(b) *The Origin, Development, and Close of the Mishna*.—During the exodus of the Jews in Babylon the sacred hope of restoration to the promised land had led to a deeper study of the Law and to a firm resolve to put it into practice whenever that restoration should be accomplished. At the head of this restoration stood Ezra, "a ready scribe in the law of Moses" (Ezra vii. 6). Not only the forms of temple worship, the many dietary laws, the laws of levitical purity, but even the agricultural regulations and the whole judicial code had to be included in the work of reconstruction. Jewish tradition ascribes the continuation of Ezra's work to the *Sopherim* (scribes) or the men of the Great Synagogue.† After these the *Sanhedrin* of Jerusalem became the chief tribunal. From its decisions there was and could be no appeal. Thus, in the course of several centuries, a vast stock of laws and usages had accumulated which the Torah (five books of Moses) did not directly authorize, but which were transmitted orally from generation to generation, and which Jewish orthodoxy refers back to the time of Moses (Oral Law). Academies arose for the propagation of this stock of tradition, and efforts began to be made to found the traditional enactments upon a biblical basis and support. This tendency received its chief impulse at the time that Sadducean opinions began to manifest themselves, and the Pharisean doctors found it imperative to emphasize their belief in the necessary development of the Law to suit the changed conditions.

* Long after the close of the Talmud a number of smaller tracts, composed in the form of the Mishna, made their appearance. They are appended to the 4th Seder under the general title of *Massekhtot*. Besides these, seven lesser tracts were edited by R. Khebiha from an ancient manuscript (*Chapter I*) *Talmud* in Greek, translated into the Hebrew, 1871. These are all of Palestinian origin, of obscure authorship, and have never been regarded as authentic.

† This has been used upon the relation of this body. See A. Kautsky, *Über die Mishna der großen Synagoge* (Amsterdam, 1895).

The suppression of the Sadducean Sanhedrin at the death of Alexander Jannai and the triumph of Pharisees at the recall of Simon ben Shetach must have given the first immediate impulse to a classification of the Oral Law. Such classification, with its anti-Sadducean tendency, was introduced in the exegesis of the Law (*Midrash*)—e. g. the method of procedure of the Sanhedrin in the exegesis of Deuteronomy. Hillel the Elder (B. C. 32) carried on this work. Installed as patriarch in Palestine, he became the head of a numerous and learned school. To him is attributed the general arrangement of the Oral Law in six divisions. It is very probable that every great teacher had his own compilation which he handed down orally to his immediate disciples. We hear especially of a Mishna of Rabbi Akiba (about 100 A. D.), the celebrated Talmudist and martyr; and the compilation of R. Meir (about 150 A. D.)—to whom are ascribed the majority of the anonymous canons in our Mishna—became the foundation of the Mishna as it now exists.*

R. Jehudah Hannasi, simply called "Rabbi" (about 160 A. D.), was the one who gave final form to the Mishna. He examined anew the vast accumulation of ordinances, abridged and amplified it where necessary, but preserved the teachings of the Fathers—in so far as they met with his approval—in exactly the form in which he had received them. Here and there a few additions were made by later teachers, but these are unimportant, and are generally to be found at the end of the tracts. Whether the division of the *Sederim* into tracts was the work of Rabbi or of his predecessors it is impossible to decide. The tracts, however, were known to the doctors of the Gemara, and Frankel has conclusively shown (*Hodegetica*, p. 264) that the Babylonian Gemara was already familiar with the division of the tracts into chapters. The arrangement of the chapters, however, in their present order is said to have been the work of the later Saboreans. The period of time which includes the men who are mentioned as authors of canons in the Mishna extends over five centuries and a half—namely, from the last of the scribes to the death of Rabbi. In the post-Mishnaic epoch the name *Tannaim* (teachers) was applied to those who had advanced opinions of their own in the disputations of the academies.

(c) *Language of the Mishna*.—This, though essentially Hebrew, differs from the more ancient Hebrew in important particulars. The natural development is shown in new and modified meanings which have sprung up side by side with the old: in the invention of new terms; in formal changes by means of which biblical words have been adapted to express new modes of thought. The influence of the Aramaic, which in the second century B. C. had become the ordinary language of the people, shows itself in the many Aramaic words received bodily into the language of the Mishna, as well as in many grammatical forms and syntactical constructions. Besides this, the spread of Grecian culture in Palestine favored the introduction of many Greek terms, and also, indirectly, of some Latin ones. Many of them, however, passed through Syrian channels on their way to Palestine, and are thus more or less modified in form.

(d) *The Composition of the Mishna*.—That the Mishna was not cast in a single mould must be plain to every one who is acquainted with its contents, form, and language. In many places the Mishna simply lays down the Law, omitting to mention the conflict of opinion that existed in regard to it. Elsewhere even the slightest diversity of opinion is noted. Certain ordinances are twice and three times repeated. One and the same ordinance is sometimes supported by totally different arguments in the different places in which it occurs. All this points to the conclusion that a considerable number of minor compilations already existed in the days of Rabbi Jehudah which he adopted, arranged, and enlarged, and in this way the general arrangement can be yet recognized. The oldest layer of Mishnas, dating back to the time of Alexander Jannai (see above), busied itself with the temple service and the court of justice. The tone is a general one, and a certain rhythm is perceptible. Their tendency was anti-Sadducean. The second layer busied itself with more minute and individual affairs. As nothing was reduced to writing, the material was arranged (1) as far as possible in the same order as the laws occur in the Pentateuch, (2) according to the outward agreement in the form of expression or in subject-matter. There are also indications by means of which the author of some

of the individual parts of the work of R. Jehudah can be discovered.

(e) *Reduction of the Mishna to Writing*.—It was a general principle with the men of the Talmud that the traditional law ought not to be committed to writing. Unity of development was threatened if each teacher were to fix in writing his own collection. There is, however, sufficient evidence to show that at an early time both Haggada (exegesis) and Halacha (law) were committed to writing. But concerning the exact time at which the Mishna was written down, great diversity of opinion prevails. Some hold that Rabbi Jehudah arranged the Mishna in his own mind and transmitted it by word of mouth to his disciples; that it was thus preserved with verbal accuracy down to the time when the academies sank in importance, and it was found necessary to fix the traditions in writing.

Some hold, with a greater show of reason, that Rabbi Jehudah himself wrote out the greater part of the Mishna in full.

(f) *Authenticity of the Mishna Text*.—The text of the Mishna has suffered much, as it has passed through the hands of many copyists and compositors. It exists at present in three recensions: one in the manuscripts and editions of the Mishna, another embodied in the Talmud of Babylon, and a third in the Talmud of Palestine. All these differ greatly, and the text which was before the ancient commentators differs from that of any of the three recensions mentioned. Frankel has shown (*Mebo*, p. 20) that even during the lifetime of R. Jehudah and soon after his death the great authorities of Palestine did not scruple to subject his work to revision. For this reason criticism of the Mishna text plays so important a part in the Gemara of Babylon and of Palestine.

(g) *Commentaries on the Mishna*.—Maimonides (twelfth century) heads the list with his commentary, written in Arabic, of which only parts have been printed (Edward Pocock, *Porta Mosis* (Oxford, 1655); J. Barth, *Maimonides Commentar zum Tractat Makkoth* (Leipzig, 1881); J. Derenbourg, *Commentaries de Maimonide*, etc. (Berlin, 1886-91); E. Weill, *Der Commentar des Maimonides zum Tractat Berachoth* (Berlin, 1891); J. Zivi, *Der Comment. des Maimonides zum Tractat Demai* (Berlin, 1891); S. Bamberger, *Commentar zum Tractat Kilajim* (Frankfurt, 1891). A Hebrew translation may be found in many editions of the Mishna and the Talmud. He was followed by R. Tanchum, of Jerusalem, who wrote a lexicon of the Mishna in Arabic (Neubauer, catalogue of Hebrew MS. cols., 534, 535). Of the many commentaries which have appeared since then, it is only necessary to mention those of Asher ben Yechiel (1327), Obadya of Bertinoro (end of fifteenth century), Yomtov Lipmann Heller (1579-1654), Jacob ben Samuel Chagis (seventeenth century), which are to be found in the different editions of the Mishna.

(h) *Translations of the Mishna*.—About the middle of the seventeenth century the desire to become acquainted with the contents of the Mishna was manifested also by Christian scholars. Translations of all or single portions of the Mishna began to appear in Latin, Spanish, Italian, French, English, and German. The most important are Guilielmus Surenhusius, *Mishna sive totius Hebraeorum juris Systema* (Amsterdam, 1698-1703); *Mishnayott*, edited by J. M. Jost (vocalized text with German transl. in Hebrew letters), Berlin, 1832-34; J. J. Rabe, *Mischnah oder der Text des Talmuds* (Ansbach, 1760-63); E. Baneth, *Mischnaiott . . . nebst Deut. Uebersetz.* (Frankfurt-on-the-Main, 1888); A. Sammt, *Mischnayott . . . mit . . . Deut. Uebers.* (Berlin, 1886); D. A. de Sola and M. J. Raphael, *Eighteen Treatises from the Mishna* (London, 1843); J. Barclay, *The Talmud* (London, 1878); *Yoma, or the Day of Atonement*, Palestine Exploration Fund, Quarterly Statement (1885); *Middoth, or the Measurements of the Temple*, *ibid* (1887). For an account of the numerous editions of the Mishna, see Fürst, *Bibliotheca Judaica*, ii., p. 40, i.; Benjacob, *Qaf Hasepharim* (1880), pp. 399 ff.

(B) *The Gemara*.—The term *Gemara* is of Aramaic origin, and its signification is the same as that of Talmud—teaching. It is also used to designate the method of deduction current in the schools as well as *tradition* itself. Ordinarily it denotes the whole body of controversies and teachings which arose in the academies after the close of the Mishna, and which, being collected in writing, now form the second and major part of the Talmud. There are two *Gemaras*, the one elaborated in the academies of Babylon, the other having Palestine for its birthplace. The customary name

* Dr. Lewy, *Ueber einige Fragmente aus der Mishna des Abba Saul*, has endeavored to show that Abba Saul (about 100 A. D.) collected a Mishna which was used in the final redaction.

given in the *halakot*, *halakot* of Jerusalem, is pronounced, as the academy which in Jerusalem after the destruction of the Temple.

(a) *The Gemara in the Babylonian Talmud*.—The *Gemara* is in general a commentary to the *Mishna*, in the words of which it attaches its discussions, explaining terms and things wherever necessary, harmonizing discrepant statements, and endeavoring to refer anonymous statements to their proper authors. Nor does the *Gemara* ever lose sight of extra-Mishnaic considerations, but disposes to state them as they may be brought into agreement with the *Mishna*. Furthermore, it formulates new ordinances, and reports in full the controversies that took place in the academies in respect to all laws and kindred subjects. For this reason the authorities who lived after the close of the *Mishna* are called *Amoraim* (expounders), in contradistinction to the *Mishnaic* authorities who are known as *Tannaim* (teachers). But the *Gemara* has also gathered the utterances which have dropped from the lips of great masters and the traditions which had been preserved of their life and actions. Thus it contains *legal enactments, homiletical sayings of scripture, games, maxims, proverbs, parables, tales, and also medical, mathematical, and astronomical data*.

The *Talmud* divides its component elements into two distinct classes. The one class includes the ritual and ceremonial, the civil and criminal laws, and also the chief heads of ethics (*Halakot*, way, custom, law; cf. *Afa* b. 2, etc.). Everything not legal is embraced under the term *Haggada* (non-Halakic interpretation of Scripture). *Haggadic* utterances are considered as individual and without binding authority, though some have become so hallowed by tradition that even the *Halakot* employ them as the basis of some of its enactments. The *Mishna* is exclusively occupied with *Halakot*. A few *Haggadic* elements are found chiefly at the end of tracts, but they are undeniably later additions. A single *Mishnaic* tract is devoted to *Haggada* (*Abot*, Sayings of the Fathers), but its distinct anti-Sadducean tendency was the cause of its early redaction.

(b) *Antient Elements in the Gemara*.—Shortly before and after the close of the *Mishna* various collections of ordinances and disputations were made, where *Halakot* was interspersed with more or less *Haggada*. A few of these (so-called *Halakic Midrash*) are still preserved, though expanded by later writers and corrupted in the course of time. They are the *Tosephta*, composed after the manner of the *Mishna*, but with discussions and explanations; the *Mechilta*, *Sifra*, and *Sifrei*—all three arranged in the form of a running commentary on *Exodus*, *Leviticus*, and *Deuteronomy*. These, and perhaps others now lost, bore the general title *Mishna* (collection of teachings), rarely *Berakot* ("productions extraneous" to the *Mishna*). These *halakic* are often quoted in the *Talmud* for the purpose of throwing light upon obscure passages in the *Mishna* or with a view to determining their own value. But certainly they are in a state of real confusion, as can be seen from many *Jerusalem* which are quoted in *Tosephta*, *Mechilta*, etc., composed with their citation in the *Gemara*.

(c) *Shape of the Two Gemaras*.—The *Gemara* of Babylon does not cover more than 37 *Mishnaic* tracts. (There are wanting in *Zerubim* 10, *Moad* 1, *Nazir* 2, *Kodushim* 2, *Pekudot* 11.) It will be seen that the tracts omitted deal mostly with matters which pertained specially to the land of Israel. The tracts of the fifth division, however, have received a commentary, because of the firm hope that a sacrifice would at some future day be introduced, and because the study of sacrificial laws was deemed equally meritorious with the performance of the sacrifice itself. It must not, however, be supposed that the omitted tracts were entirely neglected by the *Amoraim* of Babylon. They are frequently mentioned, and are often the subject of elaborate discussion.

The *Gemara* of Palestine extends over 30 tracts—i. e. over the first four books and over a part of the sixth. It is true that the text of the Palestinian *Gemara* is full of gaps, in view of which some scholars have thought that there was at one time a Palestinian *Gemara* to the whole *Mishna*. But the evidence is insufficient, and only makes it probable that a *Gemara* to the whole of *Nidda* in the sixth book (see *Tosephta* in *Nidda*, 66a) did exist at one time.

(d) *The Language of the Two Gemaras*.—*Aramaic*, which, as Nathan ha-Levi, *Prov.* 31:21, 22, says, the *Gemara* to *Mishna* and the *five smaller tracts* are wrongly added to the *Babylonian* *Gemara*.

as has been said, had become the language of the people had branched off into Eastern and Western *Aramaic*. The Jews in Babylon had introduced into the Eastern *Aramaic* a number of Hebrew words and expressions, as the Jews in the Middle Ages have done in their *Judeo-Aramaic* dialect. In the Hebrew *Aramaic* the *Babylonian Talmud* is written, but the want of good MSS. and the ignorance of experts make it difficult to study its linguistic phenomenon. The Palestinian *Gemara* is composed in the current Eastern *Aramaic*, of which these are chief representatives in the Christian Palestinian dialect and in the *Mandaitic*. The Palestinian *Gemara* has preserved more closely than the *Babylonian* the actual pronunciation of its day, in which letters belonging to the same order of speech interchange usually. It contains also a much larger quantity of Greek words than does the *Babylonian*.

(e) *The Form of Discussion in the Two Gemaras*.—In style and form both *Gemaras* exhibit the common attitude of pregnant brevity and succinctness. This is especially true in the terminology of the schools, where a single word often indicates whole sentences. As there are neither verbal nor interpretative questions, and so questions and answers are stylistically closely interwoven, it needs the practical eye of the scholar to discern where the one ends and the other begins. The Palestinian *Gemara* is still more monological. In *material* and *method* of discussion a difference is seen between the more ancient and the younger *Amoraim* of Babylon. The former aim at comprehension, and restrict themselves to plain and simple exegesis and deduction. The younger *Amoraim*, particularly since the days of Abaya and Raba (fourth century), argue rather for the sake of mental exercise. They raise artificial difficulties only for the purpose of overruling them again, and the method obtained the ascendancy in the schools against the older form and in practical cases of conflicting authority. The *Gemara* of Palestine refrained altogether from such attempts at unbridled dialectics. In its treatment of the *Haggada*, too, it is simpler and more rational; while the *Babylonian Haggada* is full of gross exaggerations; of denunciations and of witchcraft, borrowed from the Zoroastrianism that surrounded it on all sides, though it is not wanting in noble moral principles and in deep sentiments.

(f) *The Teachers of the Two Gemaras*.—From the time of the older *Amoraim* (end of third century) to the middle of the fifth century seven generations of scholars are mentioned in the *Babylonian* and six in the *Palestinian Talmud* up to the first half of the fourth century. Until the disorders of war made it impossible, an unbroken line of repeatedly had connected the schools of both countries. Young students from Babylon sought the Palestinian academies, and after years returned home with fresh materials. The reverse was sometimes the case. Thus at times we find Palestinian authorities cited in the *Babylonian Gemara*, and vice versa; but numerous inaccuracies and contradictions occur, the same ordinances being at times attributed to different *Amoraim* in the two *Gemaras*. This is often due to the corruption of the text and the similarity of names.

(g) *The Compilers of the Gemara and the Date of their Completion*.—The rapid growth of the material on the one hand and the religious persecutions under the Sassanid kings Yezdigard II. and Pabir on the other necessitated the collecting and ordering of the discussions of the *Amoraim* in Babylon. Tradition and research place this toward the close of the fifth century, and ascribe its editing to R. Ashi (head of the school in Sura from 475-497 a. d.). But R. Ashi was by no means the first, last, or only one engaged in the work. Some of the tracts differ strikingly from others, and repetitions are very numerous. At an early date attempts were made by means of mnemonic signs to give assistance to the memory, and it is very possible that many of the tracts, or parts of them, had been previously arranged by earlier *Amoraim*. R. Ashi rearranged, corrected, and perhaps completed them. Nor was the redaction finished by R. Ashi; tradition expressly mentions R. Abbina, b. (475-490 a. d.) as compiler; and authorities are quoted in the *Gemara* who lived toward the end of the fifth century. The final redaction was made under the Sassanid (the followers of the *Amoraim* in the sixth century. But the work was never formally closed. It was never intended that there should be a canon of the *Gemara*. The insertion of tracts that "further additions and extensions could no more be admitted" is a simple fiction. Not only have marginal notes crept into the text, but long passages of *Halakic* tendency and numerous *Haggadas* have been interpolated into the

Gemara. Even passages from the famous commentary of R. Yitschaki have been incorporated in the text. Indeed, in the Middle Ages it was a mooted point whether R. Ashi himself wrote down any of the Gemara. It seems impossible to believe that R. Ashi could have orally arranged so voluminous a work (ten or eleven times as large as the Mishna); and there exists an authentic tradition that R. Ashi revised the Gemara in a second edition.

Of the authorship and date of completion of the Palestinian Gemara still less is known. By an ancient tradition its authorship is ascribed to R. Jochanan (end of second century). But that is impossible, as everywhere one meets with the names of Amoraim who flourished centuries after R. Jochanan. Perhaps the tradition merely indicates that R. Jochanan was the author of the Mishna recension found in the Palestinian Gemara. J. H. Weiss has endeavored to prove that R. Jose ii. (about the middle of the fourth century) laid the foundation upon which the Palestinian Talmud was built. In regard to the date of composition the same uncertainty exists. Isaac Alfassi asserts that the authors of the Babylonian Gemara were acquainted with that of Palestine. During the Middle Ages all deferred to his authority. Jost declares that it was edited hardly 100 years after the close of the Mishna. Rappoport and Chayoth (*Mebo*, p. 28 b) agree with Alfassi. Frankel refutes their arguments; but concedes that the close of the Palestinian preceded that of the Babylonian by several centuries. Wiesner assigns to its completion so late a period as that between 760-900. Steinschneider is correct in saying that it was not edited before the last third of the fourth century (as Dioleclian, Ursicinus, and Julian are mentioned); and it probably received its final form at the time of the abolition of the patriarchate of Tiberias, in the last quarter of the fifth century.

(h) *Condition of the Text of the Gemaras.*—It is hardly to be expected that the text of the Babylonian Gemara, which has passed through the hands of so many copyists and compositors, should be very correct; but the disfigurement of the text as it stands is greater than in the case of any other work which has been handed down to us from ancient times. Three causes have occurred to bring about this result: (1) Unfortunately, the text of the Talmud was not treated with that care accorded to the biblical text. Incompetent men have inserted marginal notes in the text, have omitted whole sentences, and have confused names and things in general. Would-be critics have made uncalled-for changes in the text to suit their pleasures—an abuse already complained of by Hai Gaon. (2) Pious censors, who continued to pursue the literature of the Jews with a fanatical hatred almost to the present day, found a peculiar pleasure in venting their spite upon the Talmud. Ignorant and overzealous as most of them were, they not only expunged the few passages that refer to the founder of Christianity, but many others which they wrongly construed to be disguised attacks upon Christianity. Jewish editors themselves, in sheer self-defense, undertook to erase what a mournful experience had taught them was liable to give offense. (3) Good MSS. became very scarce, owing to the bigotry of mediæval popes. Acting upon the order of Louis IX., cartloads of the Talmud were burned in Paris 1242. Clement IV. (1265-68) sent to the Bishop of Tarragona a bull ordering that all copies of the Talmud should be handed over to the Franciscans and Dominicans, who were to burn whatever was anti-Christian. Gregory IX. in 1239 ordered the archbishops in France, Spain, and Portugal to confiscate all possible copies of the Talmud. Fortunately the passages which have been expunged or disfigured have been published separately.

Since the invention of printing not less than fifty complete editions of the Talmud have been published (see Rabinovitch, *Dikduke Soferim*, p. 42), besides hundreds of single tracts. None of these, however, can be said to contain a philologically correct text. It is true that from the sixteenth century on attempts have been made to justify the text of the Gemara, notably by such scholars as Solomon Luria (1582), Samuel Kaidonover (1697), Isaac Berlin (1800), Elia of Wilna (1797), and Akiba Eger (1837). R. Rabinovitch, in his *Variae Lectiones*, 15 vols., Munich, 1868-86, has collected a large number of variants, especially from the celebrated Munich MS. But the first systematic attempt to formulate the requirements for such an edition was made by F. Lebrecht. In 1886 the Semitic section of the Seventh Oriental Congress publicly expressed its desire in this direction. M. Friedmann has accordingly attempted such a critical edition of *Sukkoth*, but hardly with success.

A trustworthy scientific text can be gotten only by (1) a comparison of all available MSS., (2) a comparison of parallel passages in both Gemaras, (3) a collection of all the citations in the older compendia,* in the commentaries,† and in the lexicon of R. Nathan ben Yechiel. A good beginning has been made in this direction by Max L. Margolis in his *Commentarius Isaacidis quatenus ad textum Talmudis investigandum adhiberi possit* (New York, 1891); *The Columbia College MS. of Meghilla* (New York, 1892).

The Palestinian Gemara has fared still worse. The corruption of its text is visible on every page. It has not suffered so much as the Babylonian from censorial interference and from the mistakes of copyists, for during a long period it remained unknown in the schools, and even after it had become known it was barely noticed, much less critically studied by scholars. But it has suffered from want of attention and pure ignorance of the Aramaic dialect in which it is written. Its unguarded condition has caused it to be largely interpolated, especially in its Haggadic portions. Wiesner has endeavored to show that such interpolations, evidently aimed against the reputation of the great bearers of Talmudic tradition, were at times the work of the Karaites, whose chief seat was in Palestine. Though this has been denied by Geiger, S. Adler has brought additional proof of this view in his *Kobeš al Yadh*. Only one complete MS. of the Palestinian Gemara exists in Leyden and one fragment in Oxford.

(i) *The Literature of the Talmud.*—For eighteen centuries Jewish thought has almost wholly moved within a sphere of which the Talmud was the center. The more the Jews were oppressed the more fruitful did their literary activity become. It kept the soul alive while the body was almost dead. An immense literature has grown out of and around the Talmud. A bare list of such would fill a bulky volume. (For the older literature, see Steinschneider, *Jew. Lit.*, London, 1857, and *Catal. Libr. Hebræor. in Bibl. Bodliana*, Berlin, 1860. For the newer literature, Ben Jacob, *Qsar Hassepharim*, Wilna, 1880, and the ordinary bibliographies.) They may be roughly referred to the following categories: (1) Epitomes (Halachoth). (2) Commentaries, primary and secondary. (3) Novellæ (extended disputations on Talmudic topics). (4) Digests, and commentaries on them. (5) Collections of commandments (containing the Talmudic ordinances in peculiar arrangement). (6) Ritual and legal questions and answers. (7) Religious discourses. (8) Polemic and apologetic works. (9) Lexica and works of reference. (10) Collection of Proverbs. (11) Historical and bibliographical works. (12) In modern times monographs and larger treatises of a scientific character. This great literature is written mainly in rabbinical Hebrew, but a number of works have appeared in Arabic, and latterly in almost every European language.

(j) *Some Auxiliaries to the Study of the Talmud.*—Very little has been done toward the grammatical treatment of the Talmudic texts; but see S. D. Luzzatto, *Elementi Grammaticali del Caldeo Biblico e del Dialecto Talm. Babyl.*, Padua, 1865 (Germ. transl. by Krüger, Breslau, 1873; Eng. by J. S. Goldammer, New York, 1876); and the monographs of R. Rülff, *Zur Lautlehre der Aram. Talmud. Dialekte* (Breslau, 1879); I. Rosenberg, *Das Aramäische Verbum im Babyl. Talmud*, (Marburg, 1888); M. G. Landau, *Geist und Sprache der Hebräer* (Prague, 1822); G. Dalman, *Gramm. d. galiläischen Aramäische* (Leipzig, 1894).

As to lexicons, the situation is more favorable. *The Aruch*, by Rabbi Nathan, of Rome, after having been enlarged by Benjamin Musaphia and M. J. Landau, has been re-edited according to the editio princeps and some MSS. in the monumental work of A. Kohut, *Plenus Aruch* (or *Aruch completum*; 8 vols., Vienna, 1878-92). Buxtorf's *Lex. Talmudicum* has been re-edited and enlarged (though not successfully) by B. Fischer (Leipzig, 1875). See also S. M. Bondi, *Or Esther* (Dessau, 1812); A. Stein, *Talmudische Terminologie* (Prague, 1869). In modern languages should be mentioned J. Levi, *Chald. Wörterb. über die Targumim* (Leipzig, 1867); *Neuhebr. und Chald. Wörterb.* (Leipzig, 1876-89); M. Lattes, *Saggio di giunte e correzione al Lessico Talm.* (Turin, 1879); *Nuovo Saggio* (Rome, 1881); *Midrelanea Postuma*, fasc. i., ii. (Milan, 1884-85); M. Jastrow, *A Dict. of the Targumim, the Talmud, etc.* (London and New York, 1886, seq.); J. Fürst, *Glossarium Græco-Hebræum*

* Such as the *Halakhot Gedholoth*, the *Sheethoth of R. Achai Gaon*; the compendium of Alfasi; Jacob ibn Chahib's compendium of the Haggada *En Jacob*.

† Gershon ben Jehudah, Chananel, Nissim, Solomon ben Isaac (Rashi), the compilers of the Tosaphot or additions, Moses ben Maimon

(Strassburg, 1893); Arnold Darmstadter, *Le Talmud (ou Rev. Khad. Juive)*, 215, p. 106 (1885). As a general work of reference, J. Hamburger, *Hand-cyclopedia für Bibel und Talmud* (Stuttgart, 1883-86) may be mentioned. See also a paper by T. Theodores, *The Talmud*, in *Oriens College Magazine*, pp. 229-277; A. Schaefer, *On the Study of the Talmud*, *Westminster Review* (1893); and especially the learned treatise of H. S. Strack, *Einführung in den Talmud* (Leipzig, 1897; 2d ed. 1899).

Much less has been done for the Palestinian Talmud; but see Zach. Frankel, *Introduction to Talmud Hieronymianus*, *Mon. Aegyptia*, 1870; M. Schlessinger, *Das Aram. Verbum im Talmud*, Talmud (Berlin, 1889).

(b) *Translations of the Talmud*.—No work is so difficult to translate into a modern language as the Talmud. Its condensed and peculiar style makes it unintelligible to one who can not make use of it in the original. The following attempts have been made, but they are all to be used with great caution: G. E. Edvard, *Tractatus Talmudicus Archa Sora* (Hamburg, 1796); B. Ugoles, *Thesaurus (Schachin Menachoth, Tamid Sanhedrin)* (Vol. XII, 1756; vol. XXV, 1782); U. Barin, *Berachoth* (Leipzig, 1811); Joh. J. Hale, *Die Talmudische Traktat Berachoth* (Halle, 1777); E. M. Pinner, *Talmud Abot, Traktat Berachoth* (Berlin, 1842); P. C. Knecht, *Abudath Sarah* (Nuremberg, 1858); A. Sammler, *Traktat Baba Mezia* (Berlin, 1870); M. Rawice, *Der Traktat Megilla* (Frankfurt-on-the-Main, 1868); D. O. Strassman, *Der Traktat Tamid* (Halle, 1865); M. Rawice, *Der Traktat Hoeh in Nehumh* (Frankfurt-on-the-Main, 1866); Aug. Wasmuth, *Der Halak. Talmud in seinen Haupttheilen* (2 vols., Leipzig, 1866-67); A. W. Strauss, *A Translation of the Tractate Chagigah* (Cambridge, 1891); M. Rawice, *Der Traktat Sanhedrin* (Frankfurt, 1862); *Talmud in Joristh*, trans. by M. Chasmanis Narkyni Nevo (Homburg, 1884, seq.).

Of the Palestinian Talmud there is translation of seventeen tracts in B. Ugoles's *Thesaurus antiquitatum Sacrarum* (vols. xvii-xxx, Vindob., 1755-65); Meiss Schwalb, *Le Talmud de Jérusalem traduit* (Paris, 1871, seq.; Eng. trans. of vol. 1, London, 1865); M. Schwalb, *Traktat des Berachoth* (Paris, 1871); J. J. Hale, *Der Talm. Traktat Peak* . . . aus der Hieron. Gemara übersetzt (Augsburg, 1751); Aug. Wasmuth, *Der Jerus. Talmud in seinen Haggad. Bestandtheilen* (Zürich, 1869).

(c) *General Character and Importance of the Talmud*.—It is almost impossible to give in one paragraph an idea of what the Talmud is in its entire scope. From early times it has been customary to speak of the Ocean of the Talmud. The metaphor is well chosen to characterize a work so gigantic in proportions, so unique in the world's literature. It is a sea into which during many centuries have flowed the waters of Jewish life and Jewish thought. It swarms with a thousand varied forms of life. The Talmud is no dry handbook. It is an open encyclopedia of rabbinical Judaism, containing not only a digest of laws, enactments of ceremonial, moral, religious, and social character, but a record of the discussions themselves on each and all of those subjects; the history of the men who appear on its pages, their sayings and doings, and the record of the events which took place in the political life of the people during an eventful period.

The Talmud has suffered much both from its worshippers and detractors. For the great mass of Jews it has been the regulator of their every action, and has been held in as high esteem as the Bible. By its detractors it has been branded as "the product of a subtlest run mad." But a just and intelligent estimate of the great work finds hidden in its depths innumerable pearls and many priceless treasures, though at the same time much that is useless and the product of an over-developed casuistry, which the world and a large proportion of the Jews have now outlived. The Talmud is the mirror of its age, and the men of the Talmud, however exalted they may have been in intellect and character, were none the less the children of their age. The early Fathers of the Christian Church and the scholars of the Middle Ages were imbued with the same spirit of casuistry; but neither class is regarded as authoritative in matters of belief and action, but as marking an epoch in the history of the Christian Church. Modern scientific inquiry will treat the Fathers and Scholars of the Talmud as the Jewish representatives of a custom mutated in the past. It will find in the Talmud a source for the history of a great part of the Jewish mind, and will thus secure for the Talmud a place among the literary monuments of the world.

(d) *Science*.—The religion of Judaism, as represented in its Talmudic form, was a religion of life. It recognized no difference from the cradle to the grave. The Talmud, therefore, whose object it was to develop religion, to that extent had often to treat of questions of general science. The Haggada, too, offers scientific material in abundance. For the history of the different sciences there is much material buried in the discussions of the Talmud. The following branches are represented:

1. *Mathematics*.—A great many scattered allusions entire chapters of several tracts are devoted to mathematics for the purpose of fixing various religious observances. See the literature in Samsonowitch, *Hommes* (1879); Hahler, *Ueber den Talmud als Quelle für das Studium der Geschichte der Mathem.* (Jed. Litt. Hall, 21, 1882).

2. *Medicine* is treated of in numerous places in the Talmud. No complete collection of all the passages has been made; but see S. Cohn, *Die Medizin im Talmud* (Berlin, 1863); J. Wundt, *Biblisch-Talmudische Medizin* (Riga and Leipzig, 1850); Alois Bruns, *Der Aetherial im Talmud* (in *Prager Medicin. Wochenschr.*, 1870); Joseph Bergel, *Die Medizin der Talmudisten* (Leipzig, 1878).

3. *Botany* is represented in the Talmud in the discussions on the agricultural laws, etc. The whole material has been deftly collected in the excellent work of H. Lave, *Agronomische Pflanzennamen* (Leipzig, 1891).

4. *Zoology*.—See L. Lavey, *Le Zoologie des Talmud* (Frankfurt-on-the-Main, 1858); J. Bergel, *Studien über die Naturwissenschaftlichen Kenntnisse der Talmudisten* (Leipzig, 1890).

5. *Astronomy*.—In addition to scattered notices on the subject, astronomy is especially discussed in the treatise *Tractat Hoehanah* in regard to the fixing of the new moon. See S. Gotschmann, *Schwere Nacht* (Vienna, 1894).

6. *Law*.—In this direction the Talmud offers vast material, which has given rise to numerous monographs, of which the principal are Frankel, *Der Gericht. Bereich eines mündlich-talmudischen Rechts* (Berlin, 1860); *Zur Kenntnis des mündlich-talmudischen Criminals und Civilrechts* (Berlin, 1860); and *Grundrissen des mündlich-talmudischen Eherechts* (Berlin, 1860); Mayer, *Die Rechte der Israeliten, Athener und Römer* (Leipzig); J. Wimmer, *Der Baas* (Leipzig, 1864); *Das mündlich-talmudische Polizeirecht* (Leipzig, 1879); M. Morziner, *The Jewish Law of Marriage and Divorce* (Cambridge, 1884); J. J. M. Rabbinowitz, *Législation sacramentelle du Talmud* (Paris, 1879); *Législation civile du Talmud* (5 vols., Paris, 1877-80); M. Bloch, *Das mündlich-talmudische Eherecht* (Leipzig, 1890).

7. *History*.—As the Talmud contains the product of the Jewish mind for 1,000 years, it is almost the only guide for the understanding of the development of Judaism from the close of the Bible to the close of the Babylonian Exile. It also offers much archaeological material which still awaits research. For a proper insight into the origin and beginnings of Christianity, the Talmud is an invaluable source. Much that is in the New Testament, its mode of exegesis, its allusions, and the conflict between the different sects of the time can be understood only in connection with the social and scholastic life of which it was a part as portrayed in the Talmud. See Aug. Wasmuth, *Neue Beiträge zur Erklärung der Evangelien aus Talmud und Midrasch* (Göttingen, 1878); M. H. Bannet, *The Mishna as Illustrating the Gospels* (Cambridge, 1884); Ferd. Waser, *Die Lehren des Talmuds* (Leipzig, 1898); E. Schürer, *A History of the Jewish People in the Time of Christ* (New York, 1901).

8. *Geography*.—As may be expected, much geographical information, especially in regard to Palestine, Syria, and Babylonia, is contained in the Talmud. Zuntz was the first to call attention to this. See *Geographische Nachrichten* (1, pp. 151-154); Berliner, *Beiträge zur Geographie und Ethnographie Babyloniens* (Berlin, 1891); A. Kolat, *Lakes of the Holy Land* (in *Jour. Quart. Rev.*, iv, p. 399, seq.).

9. *Pedagogy*.—Even before the destruction of the Temple elementary and higher schools existed all over Palestine. The material on this subject has been collected by S. Marcus, *Zur Schulpädagogik des Talmud* (Berlin, 1895); J. Weiss, *Geschichte und Methodik d. Schulwesens im Talmud* (Stuttgart, 1892).

10. *Ethics*.—From the description of the Talmud as given here, it will be seen how difficult it is to speak of the ethics of the Talmud as a whole. As there is no system of phi-

* For the influence of the Talmud on Mohammed, see Finger, *Was hat Mohammed, etc.* (Helm. 1890); Friedland, *Beiträge zur Ethik nach der Koran* (Leipzig, 1898).

losophy or of psychology, so there is no real system of ethics contained in the Talmud. We find there the individual opinions of different teachers, living at different times and under different circumstances. It is as wrong to make the whole Talmudic Judaism responsible for certain views as it is to foist upon the official Halacha the beautiful flights of individual teachers. The terrible accusations of Wagenseil, Eisenmenger, and Rohling (where they are not directly falsified), have magnified the one, while the panegyrics of Emanuel Deutsch and S. R. Hirsch have contributed little toward arriving at a just estimate; but, on the whole, it may be truthfully said that the general ethical level of both Halacha and Haggada is a high one, reaching in many of the leading spirits of the day to the full height of moral excellency of their time, and that where it does recede from this height it is due to political and social oppression, or to an excessive use of casuistical argumentation.

Non-Jewish scholars who were acquainted with its contents, such as Reuchlin, Buxtorf, Herder, F. Delitsch, and H. Strack, have even become its strenuous defenders; and it may indeed be said that it is due to the Talmud that the long centuries of heartrending persecutions which the Jews have had to suffer have been unable to break down their spirit or degrade their intellectual, moral, and emotional life. See Ad. Lowy, *Die Tugend und Sittenlehre des Talmud* (Vienna, 1890); S. Schaffer, *Das Recht und seine Stellung zur Moral* (Frankfort, 1889); Leopold Dukes, *Rabbinische Blumenlese* (Leipzig, 1844); and cf. A. Keunen, *Volksreligion und Weltreligion* (Berlin, 1883), p. 188. See BIBLE. Revised by RICHARD GORTHEIL.

Tal'pidæ [Mod. Lat., named from *Tal'pa*, the typical genus, from Lat. *tal'pa*, mole]: a family of insectivorous mammals embracing the moles and the desmans. The ears are rudimentary, and the eyes very small; the skull is nearly smooth, and the posterior ridges are obsolete; the foramen magnum is oblong, and inclined far forward below; there are no distinct postglenoid processes; the tympanic elements form auditory bullæ; the zygomatic arches are slender rods; the teeth are in number M. $\frac{3}{1}$, P. M. $\frac{3}{1}$, C. $\frac{1}{1}$, I. $\frac{2}{1}$ $\times 2$, and also differ in development; in the upper jaw the true molars mostly (i. e. M. 1 and M. 2) have each four primary external and two primary and more elevated internal cusps, and an internal ledge bearing a cusp along its inner wall, but no secondary lower ledge behind the principal internal one; in the lower jaw the true molars have each two primary external cusps and three primary internal ones, connecting, and by their union circumscribing, triangular areas; the other teeth vary much in the several groups; the vertebrae are characteristic in that the cervicals have no hypapophyses, and the dorsal and lumbar no hyperapophyses; the sternum has a broad and keeled manubrium; the fore limbs are generally developed more than the posterior; the carpi are more or less enlarged, and have at least each an additional ossicle developed as an os intermedium; the scapulae are long and narrow. (1) The *Talpinae* include the moles, and have the body large and subcylindrical, the neck short, and the fore limbs short and very wide, and eminently adapted for digging; the skull is inflated at the pterygoid regions, and has no distinct pterygoid fossæ; the lower jaw is contracted under the ascending rami; the incisor teeth are in good number (s^2_1); the sternum has a very elongated manubrium; the clavicles are short and broad, the humeri broad, and enlarged at their angles; and the carpi have each an enlarged, sickle-shaped bone. (2) The *Myogalinae* are in external appearance considerably like the shrews or long-snouted mice; the skull is not inflated at the pterygoid regions, and has distinct pterygoid fossæ; the lower jaw is extended below under the ascending rami; the incisor teeth are in reduced number ($\frac{3}{1}$ or $\frac{1}{1}$); the sternum has a manubrium of moderate size; the clavicles are elongated; the humeri subcylindrical; and the carpi have no sickle-shaped bones. The family is entirely confined to the northern hemisphere, and each great region is characterized by peculiar forms. Of the moles, the typical species (forming the group *Talpæ*, distinguishable by dental characters) are represented by the genera *Talpa* and *Scaptonyx* in Europe and Eastern Asia, and aberrant groups (*Condylura* and *Scalops*) are exemplified by four genera in North America—viz., *Condylura*, *Scalops*, *Parascalops*, and *Scapanus*. Of the *Myogalinae*, one genus (*Desman* or *Myogale*) is represented by species in certain parts of Europe (e. g. Pyrenees) and Asia; another (*Uropsilus*) is peculiar to Southern China or Tibet; a third (*Uro-*

trichus) has species in Japan; and a fourth (*Neurotrichus*) in America W. of the Rocky Mountains. See DESMAN and MOLE.

Taluses: See PHYSIOGRAPHY.

Talvi: pseudonym for THERESE ALBERTINE LUISE ROBINSON (q. v.).

Tama: city; Tama co., Ia.: on the Chi. and N. W. and the Chi., Mil. and St. P. railways; 2 miles S. of Toledo, the county-seat, and 51 W. of Cedar Rapids (for location, see map of Iowa, ref. 5-1). It is in an agricultural region, and has a public park, 6 churches, public and parochial schools, water-works, electric-light and street-railway plants, a national bank with capital of \$50,000, a private bank, and 2 weekly papers. The city has excellent water-power, and flour, saw, and paper mills, egg-case, cigar, and broom factories, and 3 machine-shops and factories. The reservation of the Sac and Fox Indians is in the township. Pop. (1880) 1,289; (1890) 1,741; (1893) 2,027. EDITOR OF "HERALD."

Tamagawa: a river of Japan, flowing eastward into the Bay of Tokio, which it enters a few miles S. of that city. For over two centuries Tokio has received a supply of pure water from a canal cut from this river to the Yedogawa; and the water-works, with modern plant, obtain their supply from the same source. Cormorant-fishing is practiced at the Sekido ferry on this river. The finest cherry-blossoms found in the vicinity of Tokio occur at Koganei, on its banks. Hachioji, a silk-manufacturing center, is near the Tamagawa and about 25 miles from its mouth. J. M. D.

Taman'dua [= Portug., from the native name; said to be Tupi *taa*, ant + *munden*, trap]: a species of ant-eater (family *Myrmecophagidae*), found in Brazil and other parts of northeastern South America, and distinguished by its arboreal habits and long prehensile tail. The hair is short; the color of the head, shoulders, fore limbs, hind limbs outside, and tail along the middle is white; a stripe from each side of the neck over the shoulder and remaining part black. The native name has been accepted as a generic term, and the species is now known as *Tamandua tetradactyla*.

Revised by F. A. LUCAS.

Tama'qua: borough (settled in 1799, incorporated in 1832); Schuylkill co., Pa.; on the Tamaqua or Little Schuylkill river, and the Cent. of N. J. and the Phila. and Read. railways; 17 miles E. N. E. of Pottsville, the county-seat, and 40 miles N. of Reading (for location, see map of Pennsylvania, ref. 5-II). It is in a coal-mining region, and contains a public high school, 24 graded public schools, 12 churches, gravity water-works, gas and electric lights, a national bank with capital of \$100,000, a State bank with capital of \$47,130, 3 foundries and machine-shops, 2 planing-mills, flour-mill, powder-mill, screen-works, and a semi-weekly and a weekly newspaper. Pop. (1880) 5,730; (1890) 6,054; (1895) estimated, 7,000.

EDITOR OF "COURIER."

Tamarack: See HACKMATACK.

Tamarind [from Arab. *tamarhindî*, liter., Indian date; *tamar*, date (cf. Heb. *tāmār*, palm-tree) + *Hindî*, Indian, deriv. of *Hind*, India]: a beautiful leguminous tree, the *Tamarindus indica*, from Southern Asia and Africa, now naturalized in most warm regions. The pods are filled with a pleasant sour pulp, which is preserved with sugar, and is used for making a drink for fever patients, etc. Tamarind-pulp contains citric, tartaric, and malic acids, potash, sugar, vegetable jelly, etc. As a salt of copper is a common adulteration, a piece of polished iron (as a knife) should be left in the pulp for about an hour, when, if copper be present, it will be deposited on the iron. Tamarind-pulp is refrigerant and gently laxative, and is employed in the diseases of children. The tree is sparingly grown in Southern Florida and along the north shore of the Gulf of Mexico. The wood is very hard and handsome.

Revised by L. H. BAILEY.

Tamarind (*Tamarindus indica*).

Tamarisk Family [named from Lat. *Tamarix*, *cedr*, *cedar*; of *Tamarix*, *cedr*, a kind of tree]; the *Tamaricaceae*, a small group of about forty-five species of dioecious shrubs or trees, mostly of the temperate and subtemperate regions of the northern hemisphere, with regular hermaphrodite flowers, having five sepals, five petals, five to many stamens, and a superior one-sided, many-ovuled, three to five carpellary ovary. The leaves are alternate and small, often scale-like. The most important genus is *Tamarix*, which includes about twenty species, several of which are cultivated for their pretty pink flowers and beautiful foliage—e. g., *T. arbuscula*, *T. dioica*, *T. parviflora*, *T. tetrandra*, and *T. gallica*, the common tamarisk, which has run into many varieties. An interesting relationship has been shown to exist between this family and the Willow Family (q. v.), in which the flowers are simplified from the tamarisk type.

Tamarix dioica (Tamarisk flower).

CHARLES K. HANNEY.

Tamalapa, *lala-mur-lá-pá-sa*: town and port on the east coast of Madagascar; lat. 18° 10' S., lon. 49° 28' E., 100 miles E. N. E. of Tamatave, with which it is connected by telegraph (see map of Africa, ref. 8-11). It is on a sandbar between the port and the ocean, and is considered insalubrious. The port has deep water, but is ill protected and dangerous of access. Extensive improvements have been authorized by the Hova government. The trade is large, and the exports consist of cattle, swine, skins, rice, tobacco, copal, raw silk, mats, baskets, woods, especially the violet ebony wood. There are several important business houses. Pop. about 7,000, of which 3,000 are foreigners, including French, British, Hindus, natives of the U. S., and natives of the Mascarene islands.

M. W. H.

Tamaulipas, *lala-mur-lá-pá-sa*: a northeastern state of Mexico, bordering on Texas, the Gulf of Mexico, Vera Cruz, San Luis Potosí, Nuevo León, and Coahuila. Area, 26,629 sq. miles. Nearly all the surface consists of plains and low rolling lands with occasional hills, resembling the coast-belt of southern Texas, and, like it, bordered by extensive lagoons and salt-marshes. The southwestern part alone is included in the Mexican plateau, which here rises to about 4,000 feet; this is bordered by low mountains of the eastern Sierra Madre, and their well-watered slopes are the densest and most thickly inhabited portions of the state. The climate of the plains is essentially tropical, and the coast region is hot and often insalubrious during the summer months; much of the land is too dry for tillage without irrigation. The mountain region has a temperate and healthful climate with abundant rains; portions of forest remain, principally on the higher slopes. Besides the Rio Grande, which forms the northern boundary, and the Pánuco on the S., the state has several considerable rivers. Agriculture and grazing are almost the only industries; but sugar, cotton, and hides are exported, and coffee-raising has some little prominence. There are no mines of importance, though silver, coal, petroleum, etc., are reported. Pop. (1890) estimated, 173,300. Capital, Ciudad Victoria. The principal ports are Tampico and Bagdad, the port of Matamoros. A strip, nominally 20 km. wide, along the northern frontier constitutes the *Zona Libre*, or Free Zone; this was established by the state in 1858, and has been extended by the general Government to the entire northern frontier of Mexico. Imports for use in the zone (except cattle pay only 10 per cent. of the ordinary duties. The Mexican authorities claim that this arrangement is necessitated by the retail trade across the frontier; the U. S. customs officers, on the contrary, have frequently complained that it encourages smuggling.

HENRY R. SURIN.

Tamboff: government of European Russia, in the southwestern part of the empire, on the Uka. Area, 25,719 sq.

miles. Pop. (1890) 2,520,000. There are large forests yielding fine timber and excellent pasturage. The grain crops are large, especially in the southern portions. Woods, tall, tall, yellow, and stumps are largely manufactured.

Tamboff: capital of the government of Tamboff, European Russia; on the Volga; founded in 1860 (see map of Russia, ref. 8-11). It is well built, with low wooden houses that are surrounded by gardens. It has a college, an ecclesiastical seminary, a high school for ladies, a military academy, and several other educational institutions, and has an active trade in the products of the district. Pop. (1890) 40,676.

Revised by M. W. HANNEY.

Tambora. See SUMBAWA.

Tambourine (from Fr. *tambourin*, *drum*, of *tambour*, *drum* (O. Fr. *tambor* from Arab. and Pers. *tambor*, kind of lute or guitar, and Pers. *tabor*, *drum*); a musical instrument resembling a drum, consisting of a wooden or metallic hoop over which a parchment is stretched, and furnished with a set of bells. It is held in one hand, and beaten with the knuckles or fingers of the other hand, or sometimes also with the elbow. It has been in use from time immemorial in the Balearic provinces of Spain and in the retired regions of Italy, especially in the Abruzzi, and is well known from its employment by gypsies and wandering musicians, being a favorite instrument for accompanying their dances. It also figures prominently in the music of the Salvation Army.

TAMERLANE (See TIMUR).

Tamil Language (See DRAVIDIAN LANGUAGES).

Tammany Society: a political society in New York, founded by an Irishman named Mancy, May 13, 1798. It derived its name from a Delaware chieftain who for his reputed virtues was in the latter years of the Revolution facetiously chosen patron saint of the new republic. Organized ostensibly for charitable purposes, it nevertheless had a definite political character from the first, representing the views of an aristocracy and the distrust of Hamilton's policy felt by the thoroughgoing Democrats of the time. Secret societies under the auspices of St. Tammany were organized in Philadelphia and other cities, but the institution soon fell into disfavor except in New York, where it was soon turned to account as a political lever, and it ultimately became the principal instrument of the managers of the Democratic party in New York, exerting a considerable influence also upon State politics, and to a less extent on national politics. The society was much discredited by the participation in its honors of WILLIAM M. TWEED (q. v.) and his accomplices in fraud, but it was reorganized, and to some extent reformed, after the Tweed prosecutions.

Tammuz [Heb., from Babylonian *Dumuz*, *Dum*]; a god of Babylonian origin, whose death the Jewishish women are said to have bewailed (Ezek. viii. 14). A similar lamentation has been found in the cuneiform literature. Tammuz represents the spring vegetation which comes to an end in the fourth month. For this reason the Babylonians named that month after the god; and with the other names of the months, the Jews took this one from the Babylonians. There is, no doubt, some connection between the cult of Tammuz and that of the Greek Adonis (*Adōn* = lord), which the old writers expressly connect with the Oront. The real home of the Adonis worship seems to have been Syria and Southern Asia Minor, though it appears as early as the seventh century B. C. in purely Greek countries. Whatever its origin may be, its later forms were undoubtedly influenced by the East. That sexual excesses were connected with the worship of Tammuz is evident from the phallus which still plays a part in the modern Persian festival of Husein, which Erdman has shown to contain remnants of the old Tammuz worship.

RICHARD GORTNER.

Tampa: city; port of entry; capital of Hillsborough co., Fla.; at the head of Tampa Bay at mouth of the Hillsborough river; on the Fla. Cent. and Pac., the Seaboard, Fla. and W., and the Silver Spr., Ocala and Gulf railways; 90 miles from the Gulf of Mexico (for location, see map of Florida, ref. 6-1). It has an excellent harbor, with 22 feet of water at the outer bar, mean tide, and has steamship connection with New York, New Orleans, Mobile, Havana, Puerto Cortes (Honduras), Key West, and other ports. There are 17 churches, 7 public and 8 private schools, 2 national banks, with combined capital of \$150,000, 3 daily and 8 weekly newspapers, electric-light and street-railway plants, and a spring-water supply with daily capacity of 3,000,000 gal.

The principal industry is the manufacture of cigars, which has 120 establishments, employs 4,000 persons, and turns out goods of an annual value of \$6,000,000. In 1894 the internal revenue collections aggregated \$185,000, and the custom-house collections \$600,000. During the year 35,000 tons of phosphate were shipped to domestic ports and 105,000 tons to foreign. The city has hotel property valued at \$3,000,000. Tampa was made a port of entry in 1886, and has grown rapidly since. Pop. (1880) 720; (1890) 5,532; (1894) estimated, 16,000. EDITOR OF "TRIBUNE."

Tampa Bay: a body of water on the west coast of Florida, chiefly in Hillsboro County. Its upper portion is divided into two parts, Old Tampa Bay and Hillsboro Bay. It is some 35 miles long and from 6 to 15 miles wide. A line of keys fences its entrance from storms, so that it constitutes a safe, spacious, accessible, and excellent harbor. The bay contains many small islands, and abounds in fish and turtle. On Egmont Key, at the entrance, is a brick lighthouse 86 feet high, lat. 27° 36' N., lon. 82° 45' 15" W.

Tampico, *taám-pee'kō*: town and port of the state of Tamaulipas, Mexico; a short distance above the mouth of the Pánuco river, which divides Tamaulipas from Vera Cruz; terminus of railways to Monterey and San Luis Potosí (see map of Mexico, ref. 6-H). The harbor, formed by the river, has been made good and safe by extensive improvements, including a breakwater and jetty, so that vessels drawing 24 feet of water may enter the harbor. The town is built on flat land surrounded by swamps; in the summer it is hot and unhealthy, but less so than Vera Cruz. The Pánuco and its branch, the Tamesí, are navigated for some distance by small steamers, and there is a canal to afford inland communication between Tampico and Tuxpan, Vera Cruz, through the lagoon of Tamiahua. Tampico was opened as a port in 1823, when the fort in Vera Cruz was still held by the Spaniards. During the frequent blockades of Vera Cruz it has been the most important gulf port of Mexico, and its trade is increasing. Pop. (1889) 11,680. HERBERT H. SMITH.

Tamsui, *taám'sōó'-ēē* [literally, fresh water (town)]: a treaty-port of Formosa, on the north end of the island, in the hien or district called Changhwa; lat. 25° 10' N., lon. 101° 26' E. (see map of China, ref. 7-K). It lies between a double-peaked hill of about 1,700 feet on the S. W., and the Tamsui range of mountains (2,800 feet), which extend far into the interior, and is distant about 13 miles from the large trading-town of Bangka. The anchorage is poor, and has at its mouth a bar covered with 10 feet of water at low tide. The water-supply of the town is remarkable for its excellence, being obtained from a mountain stream 8 miles inland from Bangka, and conducted to the city by a tunnel cut in the solid rock, and a wooden aqueduct 8 feet wide and 5 feet deep supported on crutches 30 feet above the surface of the water of an affluent which it has to cross in its course. The village of Kien-pai and the towns of Bangka and Twa-tu-tia are supplied from the same sources. Tamsui (which includes Kilung, 29 miles to the E.) imports cotton and woolen goods, opium, metals, matches, kerosene oil, rice, beans, native cloth, joss-sticks, etc.; and exports, among other things, camphor, tea, and coal. In 1893 the foreign imports amounted to 2,137,805 haikwan or custom-house taels (= \$2,244,695), and the native 947,417 taels; while the exports were valued at 5,197,652 taels. Pop. 100,000.

Tana: See DEMBEA.

Tanagers [from Mod. Lat. *Tanagra*, from Braz. *tan-gara*, a bird of the tanager kind]: the *Tanagridæ*, a family of passerine birds, having, as a rule, a thick, conical, triangular bill with the cutting edges not much inflected, and generally notched or toothed behind the tip; the angle of chin is not far forward; the nostrils are placed very high; the wings are moderate, angulated, have nine primaries, and

the inner secondaries are not produced. They are related to the *Fringillidæ*, with which they should probably be united. The colors are in almost all the species quite brilliant. The group is peculiar to the New World and is chiefly developed in the tropical regions. Over 50 species have been described, arranged under forty genera. One genus (*Piranga*) is represented in the U. S. by five species, the most conspicuous of which are the red-headed tanager (*Piranga erythromelas*) and summer red (*Piranga rubra*). The species feed upon grains as well as insects, etc.

Revised by F. A. LUCAS.

Tan'agra Figurines: statuettes and groups of terra-cotta found since 1873 among the ruins of Tanagra in modern province of Boeotia, Greece. The name is loosely for statuettes and groups, fragments of which found at other places, in Sicily, Southern Italy, North Egypt, as well as in Greece proper. In all the countries colonized or influenced by the ancient Greeks these figures were once as common as the painted vases which are so valuable to modern students, and Tanagra was only one, though an important one, of the many towns where ceramic work was carried on. Thus outside the walls of Smyrna in Asia Minor are rubbish heaps from which have been brought hundreds of delicately finished heads in terra-cotta, the bodies being often left behind as unimportant. Many earthenware figures are found in tombs, but it does not follow that they were made, like the thin gold jewelry found in similar tombs, for interment with the body. It is more likely that they were buried as the favorite works of art of the deceased, or in some cases as portraits of friends. It is the theory of some archaeologists that the veiled female figures represent goddesses of the dead, as Persephone. Many of the statuettes are colored in an elaborate fashion, but this coloring is rarely fired so as to form true keram painting; it is therefore very perishable. These painted statuettes generally bring the highest prices when offered for sale. As the laws of the Turkish empire and of Greece against the exportation of works of art have not long been enforced, and as these figures are small and easily concealed, thousands of them have been sold in Europe; and the great number of these have passed into private hands. The museums of Europe and the U. S. have also fine examples.

The greater number of the figures discovered are standing, draped female figures from 6 to 9 inches high. They have been generally made in moulds, with the head alone showing signs of being finished by hand and much more carefully. The back of the figure, the drapery, etc., is generally much less carefully modeled than the front. Moulds have been found exactly corresponding to some of them. Groups of two or three figures are not uncommon, and some of these are curiously made like *appliques*, that is, with the back absolutely flat and blank, the whole group having one face only, as if a bas-relief of which the background had been cut away and removed.

Very few instances of the copying of important Greek statues are known among these terra-cottas, but these figures have given to the modern world a very important instance of what might be called *genre* sculpture among the ancients, fanciful, graceful, sometimes humorous, sometimes pathetic, and of a domestic sort. The theory cited above, that many of the pieces are religious in character, is not contrary to the evidently decorative and fanciful character of others. Many modern copies exist, sometimes made in the ancient moulds, and it has become difficult to distinguish the genuine ancient specimens. For treatises upon the subject, see A. S. Murray's *Handbook of Grecian Archaeology*; the *Monuments Grecs*, a kind of periodical published in Paris; Rayet's *Art Antique*, which has splendid photographic plates; Kekule's *Griechische Thonfiguren aus Tanagra* (Stuttgart, 1878); and many papers in the *Gazette des Beaux-Arts* and in other artistic and archaeological periodicals. RUSSELL STURGIS.

Tananarivo: capital of Madagascar. See ANTANANARIVO.
